# **AE 45780: Spacecraft Dynamics and Control**

**Fall 1401**

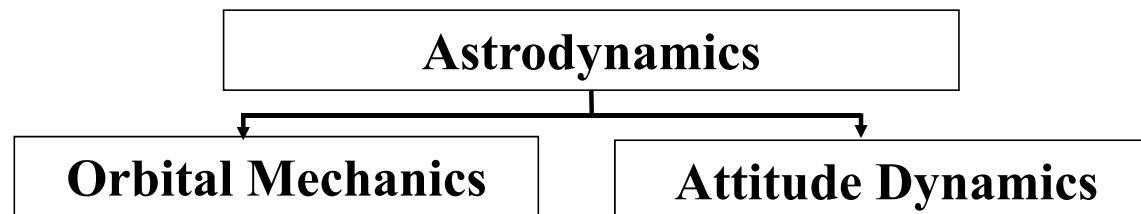

## **Chapter One**

### **Introduction and Review of Orbital Mechanics**

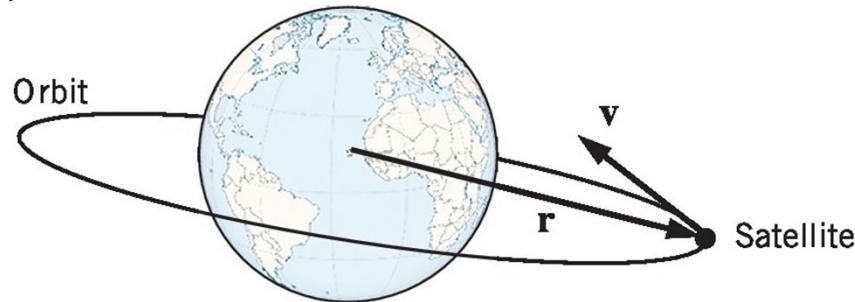

**Seid H. Pourtakdoust**

---

# Introduction and review

**Orbital Mechanics (OM) or Celestial Mechanics** pertains to the translational motions of artificial satellites/spacecraft and or natural bodies moving under the influence of forces such as gravity, atmosphere, third body, Solar radiation, thrust, etc.

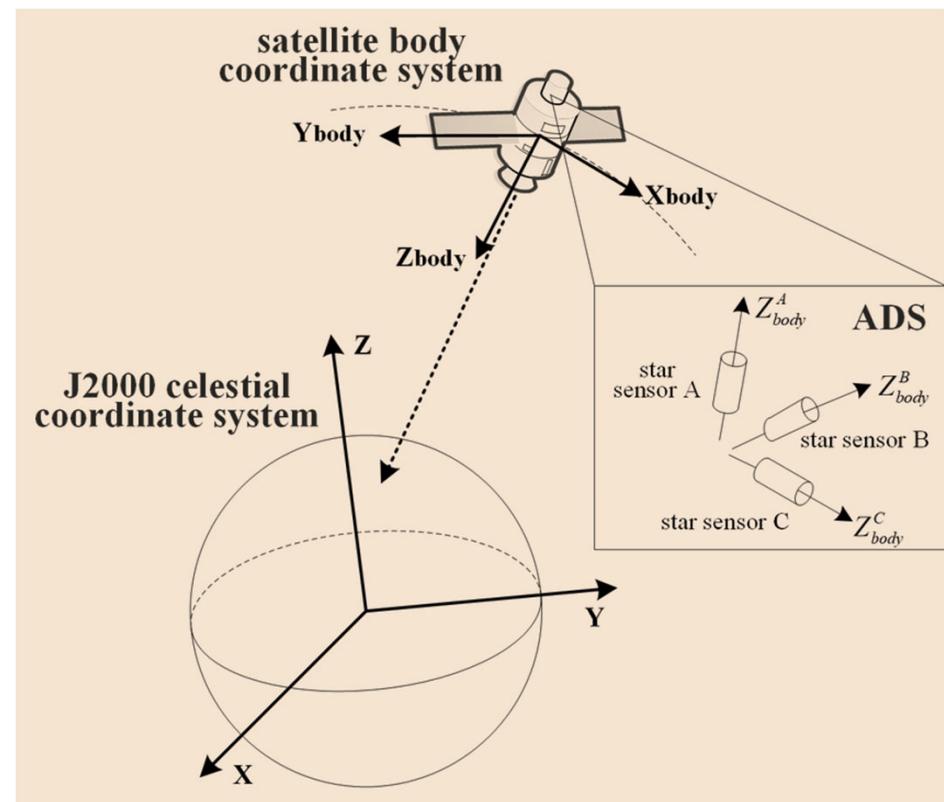

**Attitude Dynamics (AD)**, on the other hand is usually referred to the study of rotational motions of satellites/spacecrafts about their center of mass. This topic will be discussed later in the course.

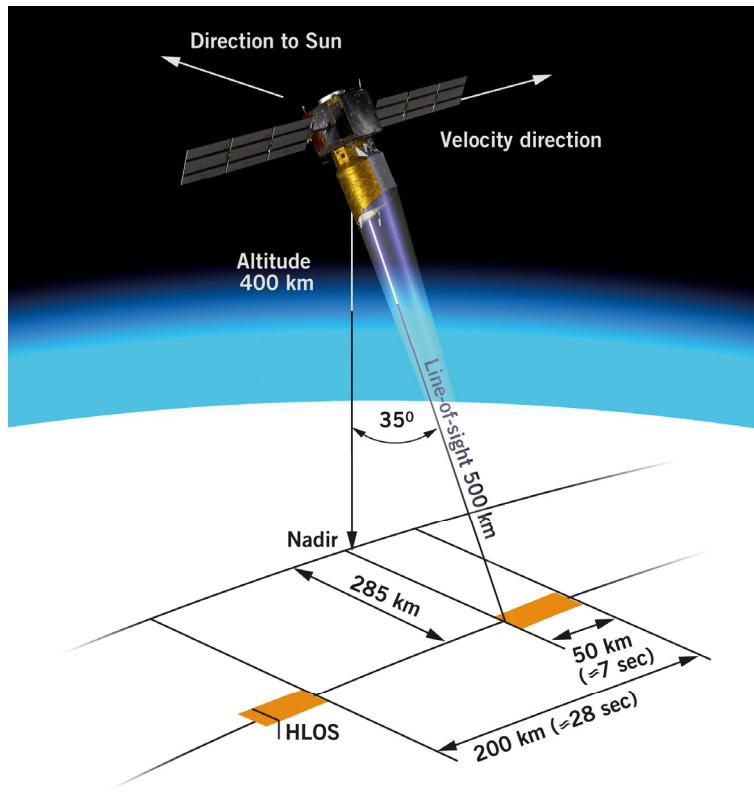

# Introduction and review

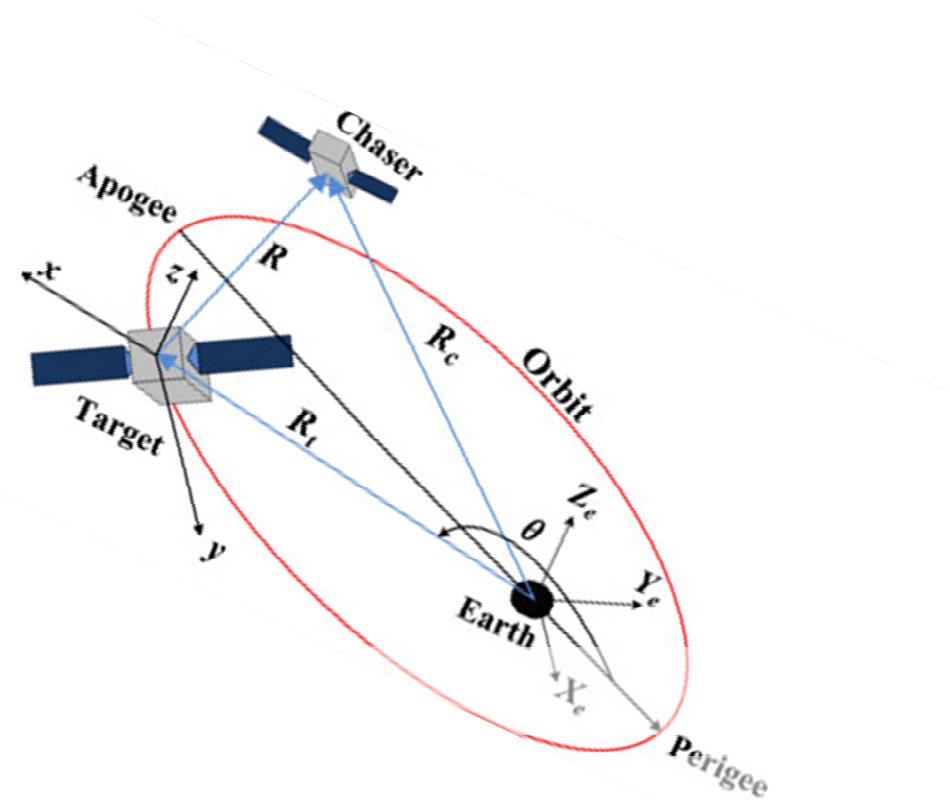

**Attitude control (AC)** is the process of controlling the orientation of a space vehicle with respect to a reference frame . AC requires sensors to measure vehicle orientation, actuators to apply the torques needed to orient the vehicle to a desired attitude and algorithms to compute the actuators command. The integrated field that studies the combination of sensors, actuators and algorithms is called guidance, navigation and control (GNC). AC as applicable to spacecrafts will also be introduced in this course.

# Introduction and review

Attitude Control

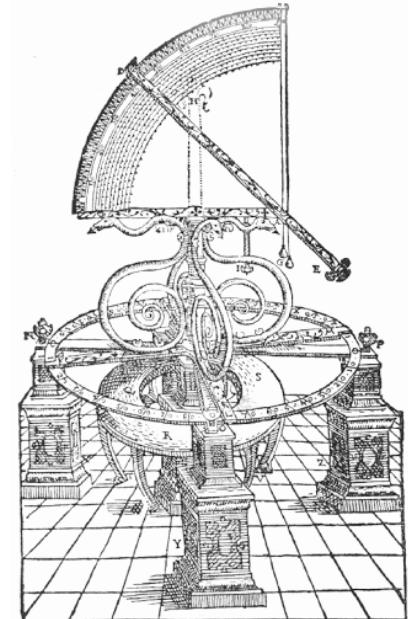

Orbit Control

## Historical Background

---

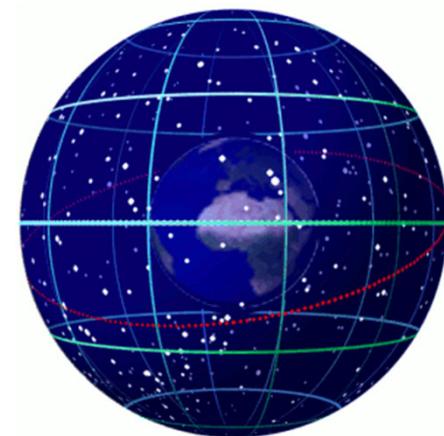

**Tycho Brahe** : 1546 –1601 was a Danish astronomer known for his accurate and comprehensive [astronomical](#) observations of planet orbits. His assistant, Johannes Kepler later used his astronomical data to discover **Kepler's** laws of planetary motion.

Tycho's Brass Azimuthal Quadrant

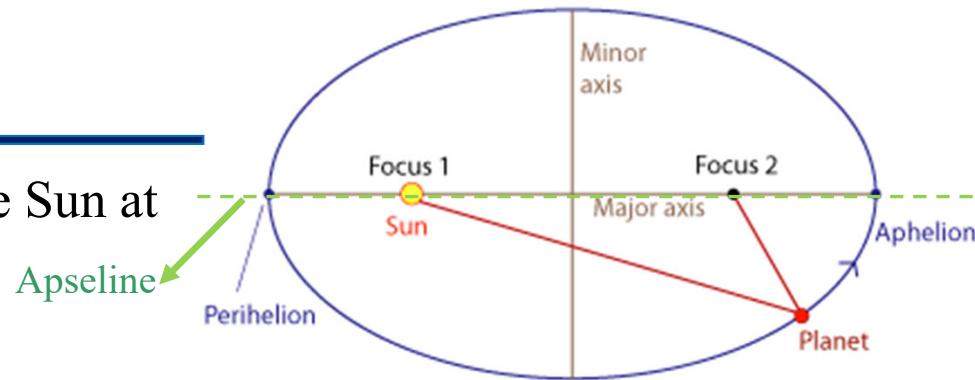

**Johannes Kepler** : 1571-1630 was an astrologer, mathematician and German astronomer. He is known for his three **laws of planetary motion**, as well as his books. His discoveries have formed the basis for Newton's theory of universal gravitation.

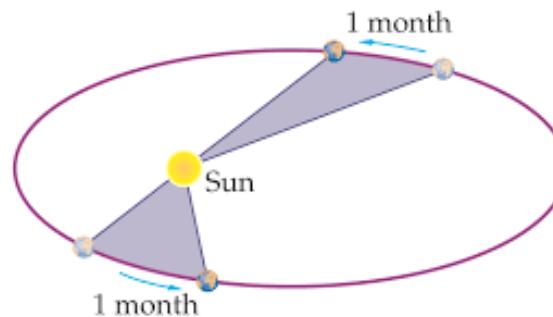

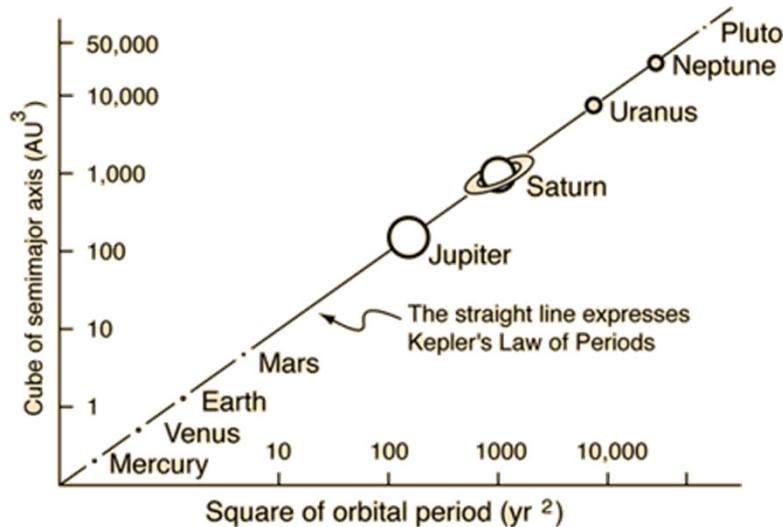

[Celestial Sphere](#)

## KEPLER'S LAW OF PLANETARY MOTION (Based on Observation)

- 1 The orbit of each planet is an ellipse with the Sun at one focus (1609).

- 2 The line joining each planet to Sun sweeps out equal areas in equal times (1609).

- 3 The square of the period of a planet is proportional to the cubic of its mean distance to the Sun (1619).

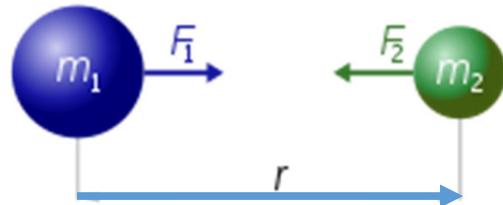

$$\tau^2 \propto r^3 \quad \text{or} \quad \tau \propto r^{\frac{3}{2}}$$

# Newton's Law and Gravity Parameter

## 4 Law of Universal Gravitation

$$F_g = G \frac{m_1 m_2}{r^2}, \quad \vec{F}_2 = \vec{F}_{12} = -G \frac{m_1 m_2}{r^2} \hat{u}_r = -G \frac{m_1 m_2}{r^3} \vec{r}$$

$$G = 6.6742 e-11 \text{ Nm}^2 / \text{kg}^2$$

*Weight of a mass m, is considered as Gravity Pull of the Planet (with the mass M)*

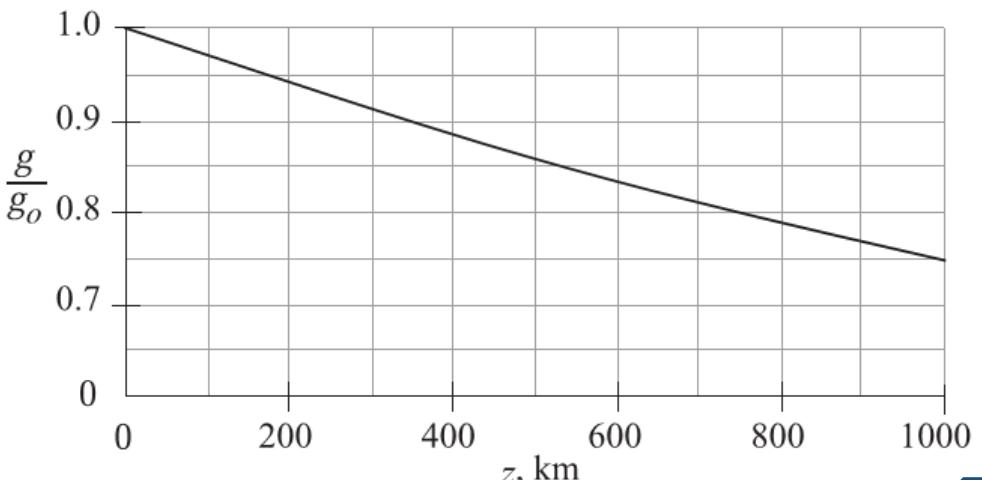

$$F_g = W = G \frac{Mm}{r^2} = m \left( \frac{GM}{r^2} \right) = mg = m \frac{\mu}{r^2}; \text{ so } \mu = GM$$

$$\text{For the Earth : } g_0 = \frac{GM}{R_E^2}; \quad r = R_E + z$$

$$g = \frac{\mu}{r^2} = \frac{\mu}{(R_E + z)^2} = \frac{\mu}{R_E^2 (1 + z/R_E)^2}$$

$$\text{Or : } g = \frac{g_0}{(1 + z/R_E)^2}$$

$$\mu_E = \mu_{\oplus} = GM_{\oplus} = 3.986004415e+5 \text{ km}^3 / \text{s}^2$$

# Newton's Laws

---

Digress: When the gravity pull is balanced?

*Weight of a mass m, as Gravity Pull of the Earth with the mass M*

$$F_g = W = G \frac{Mm}{r^2} = m \left( \frac{GM}{r^2} \right) = mg = m \frac{\mu}{r^2}$$

$\mu = GM$ ;  $\frac{\mu}{r^2} \triangleq$  Gravitational Acceleration

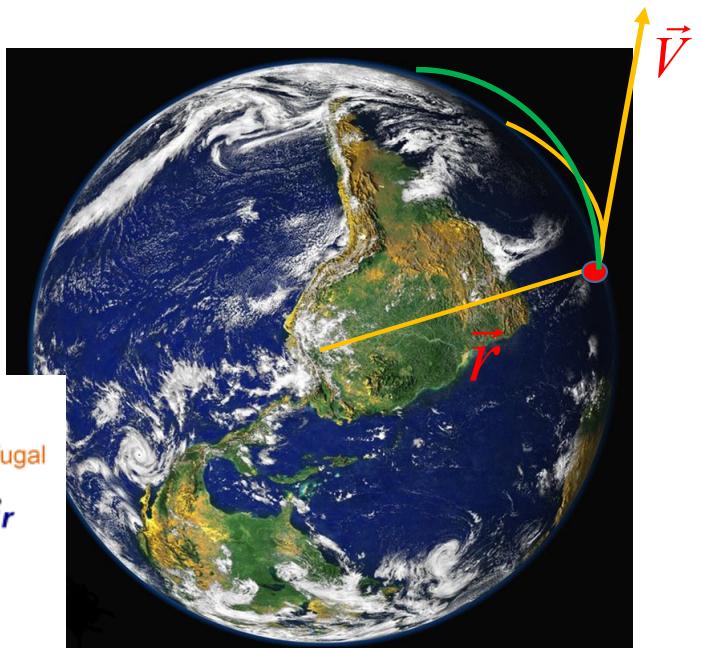

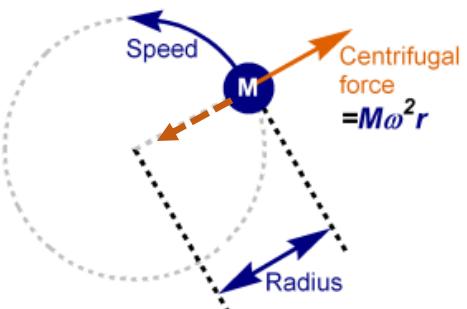

$$\mu_E = \mu_{\oplus} = GM_{\oplus} \stackrel{EGM\ 2008}{=} 3.986004415e+5 \text{ km}^3 / \text{s}^2$$

$F_g = F_c$ ;  $F_c \triangleq$  Centrifugal Force

$$m \frac{\mu}{r^2} = mr\omega^2 = m \frac{V^2}{r}$$

$$\frac{\mu}{r^2} = \frac{V^2}{r} \Rightarrow V_c = \sqrt{\frac{\mu}{r}} \triangleq \text{Circular Velocity}$$

$$\text{at } R_E \Rightarrow V_c = 25936 \text{ fps} \approx \text{Mach} = 23!$$

# Orbital Mechanics and the Two Body Problem

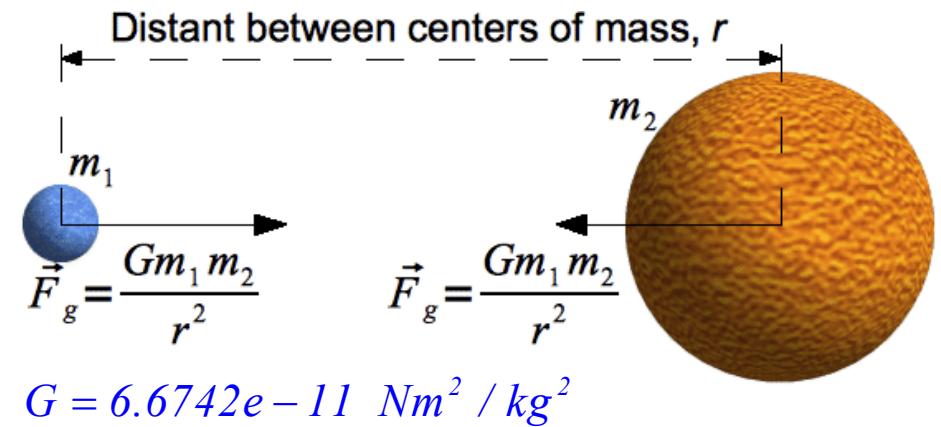

**OM** roots back to the 17th when Newton (1642-1727) formulated his law of **Universal Gravitation**. A consequence of this law, analytical solutions to what is called the two body problem (2BP) have evolved both in **three dimensions or within the orbital plane**.

*2BP Governing Equation of Motion*

$$\ddot{\vec{r}} = -\frac{\mu}{r^3} \vec{r}$$

$$\mu_{Earth} = 398,600 \text{ km}^3 / \text{s}^2$$

$$IC: \vec{r}(0), \dot{\vec{r}}(0) \Rightarrow \vec{r}(t)$$

$$G = 6.6742e-11 \text{ Nm}^2 / \text{kg}^2$$

**Universal Law of Gravitation :**

Every particle in the universe attracts every other particle with a force along a line joining them. The force is directly proportional to the product of their masses and inversely proportional to the square of the distance between them.

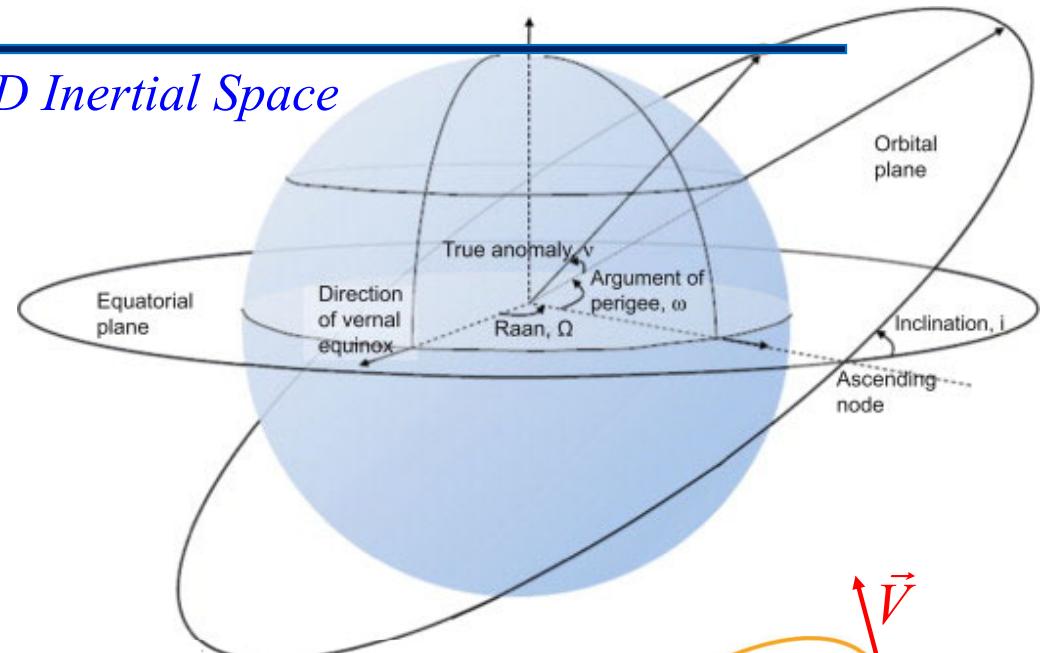

# Orbital Mechanics

## 1. 2BP Governing Equation of Motion in 3D Inertial Space

$$\ddot{\vec{r}} = -\frac{\mu}{r^3} \vec{r}$$

$$\mu_{Earth} = 398,600 \text{ km}^3/\text{s}^2$$

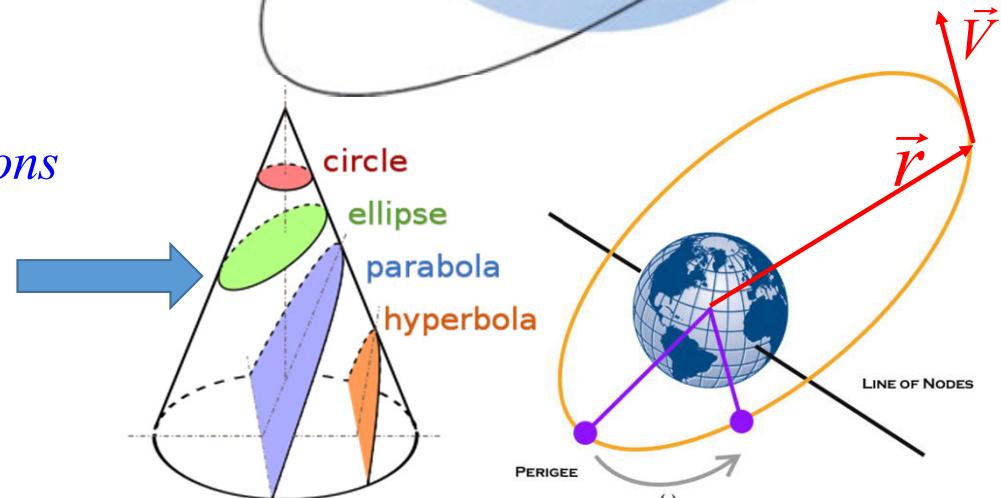

$$IC: \vec{r}(0), \dot{\vec{r}}(0) \Rightarrow \vec{r}(t)$$

## 2. Planar 2BP EOM in Polar Form:

$$r = \frac{P}{1 + e \cos \theta} ; \text{ Represents Conic Sections}$$

This equation shows the orbital motion in a 2D polar coordinate whose origin is centered at the center of mass of the Planet or Celestial body.

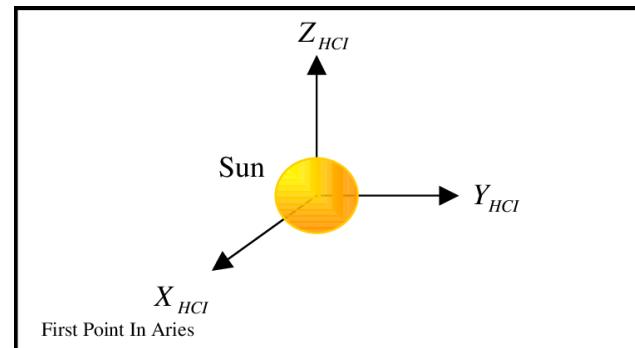

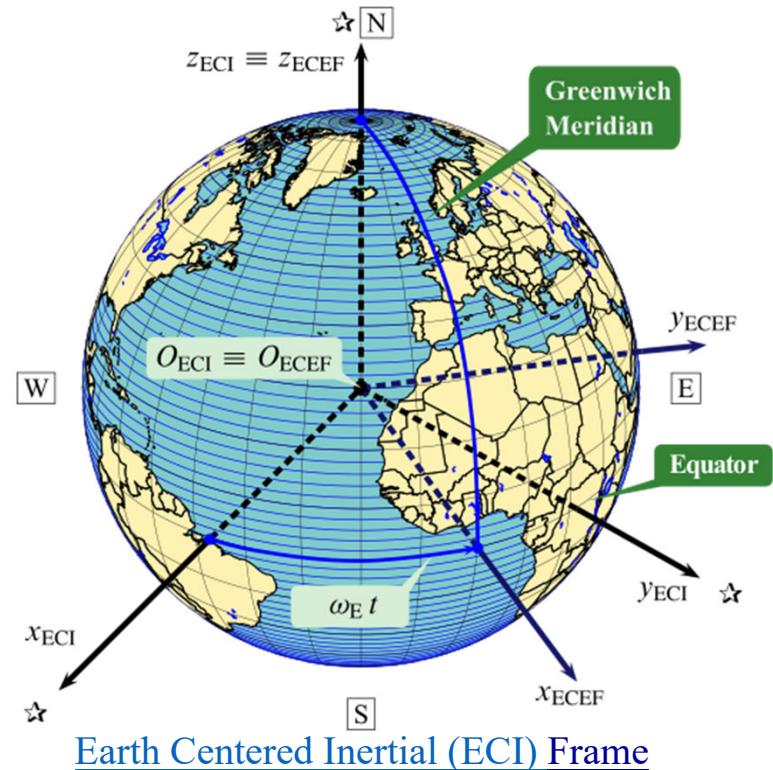

# Validity of the Newton's Laws

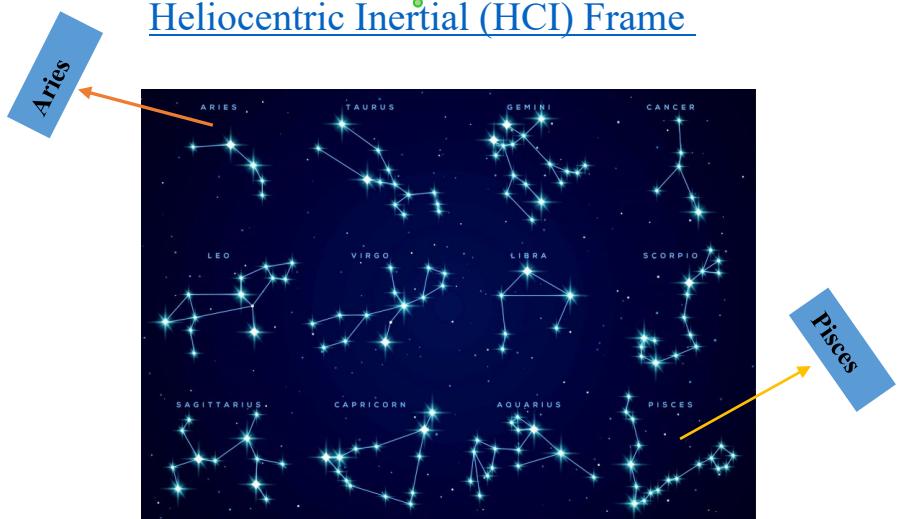

## Inertial Coordinate System (ICS)

Requirements :

- The center must not accelerate
- It must not be rotating (axes)

Heliocentric Inertial (HCI) Frame

Constellations are used as fixed points for ICS

# Derivation of the Two Body Problem (2BP) EOM in 3D Space

Using the Newton's 2nd law for the two masses :

$$m_1 \ddot{\mathbf{R}}_1 = \frac{G m_1 m_2 \mathbf{r}}{r^3}; \quad m_2 \ddot{\mathbf{R}}_2 = -\frac{G m_1 m_2 \mathbf{r}}{r^3}$$

Now consider the Relative motion of  $m_2$  WRT  $m_1$  :

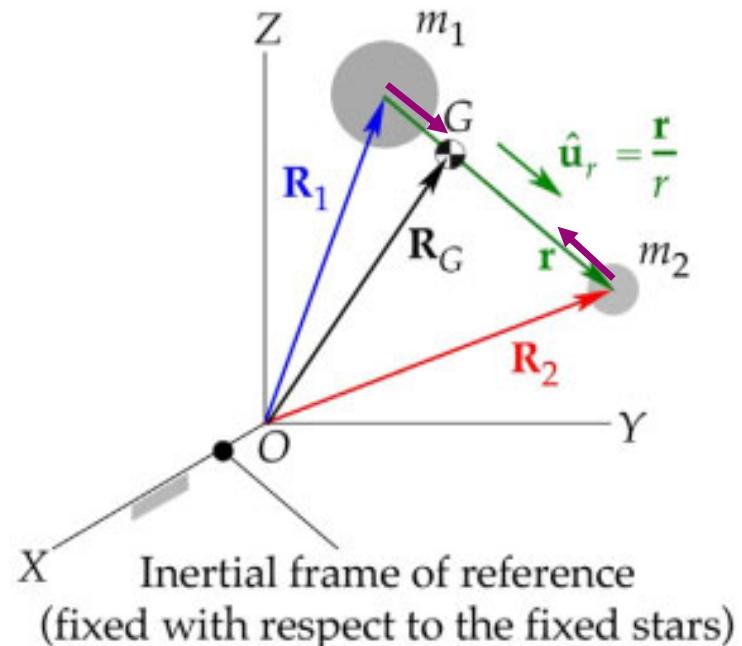

$$\mathbf{r} = \mathbf{R}_2 - \mathbf{R}_1 \rightarrow \ddot{\mathbf{r}} = \ddot{\mathbf{R}}_2 - \ddot{\mathbf{R}}_1$$

$$\Rightarrow \ddot{\mathbf{r}} = -G \frac{m_1}{r^3} \mathbf{r} - G \frac{m_2}{r^3} \mathbf{r} = -G \frac{m_1 + m_2}{r^3} \mathbf{r}$$

$$\mu = G(m_1 + m_2) \approx Gm_1; \text{ for } m_2 \ll m_1 \text{ (Earth mass)}$$

$$\Rightarrow \text{2BP EOM in 3D ICS: } \ddot{\mathbf{r}} = -\frac{\mu \mathbf{r}}{r^3}$$

$$\mu_E = 3.986012e+5 \text{ km}^3 / \text{s}^2; \quad m_E = 5.924e+24 \text{ kg}$$

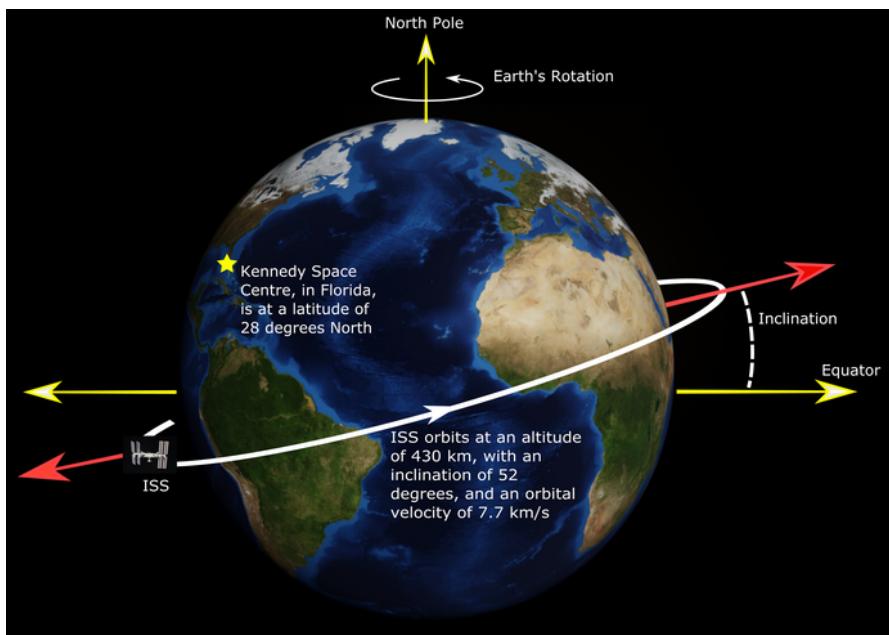

# Two Body Problem (2BP) in 3D and 2D

$$2BP \text{ EOM in 3D ICS: } \ddot{\mathbf{r}} = -\frac{\mu \mathbf{r}}{r^3}$$

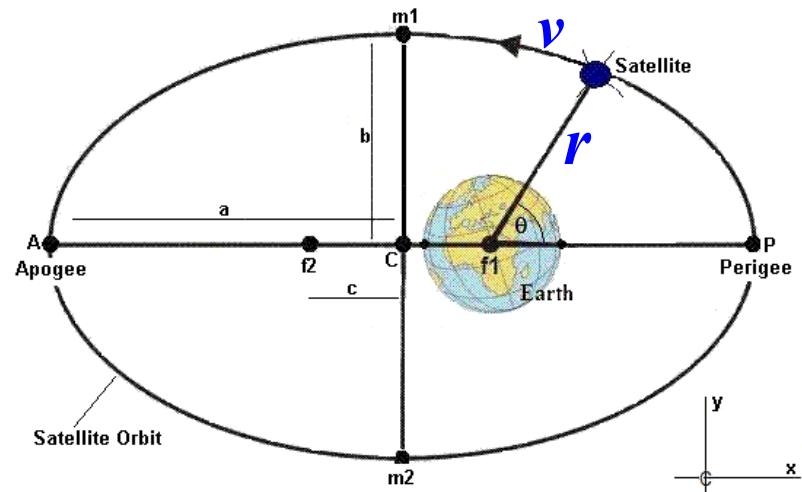

with :  $\mathbf{r}(0), \dot{\mathbf{r}}(0) \Rightarrow \mathbf{r}(t)$

$$\mu_E = 3.986012e+5 \text{ km}^3 / \text{s}^2$$

$$\text{Planar (2D) 2BP EOM: } r = \frac{P}{1 + e \cos \theta}$$

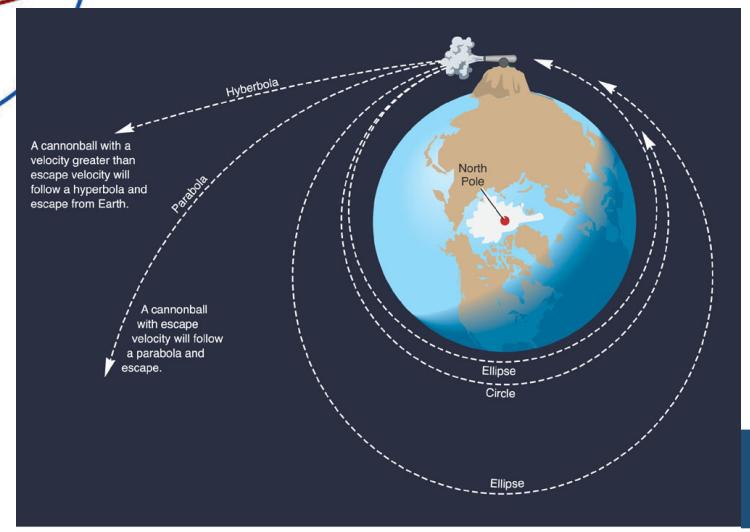

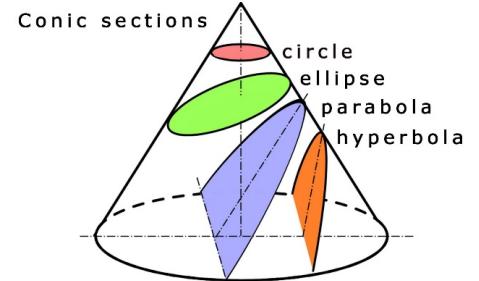

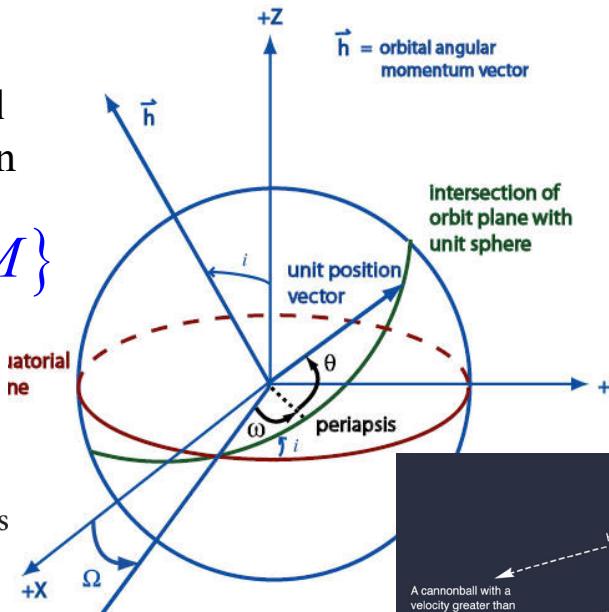

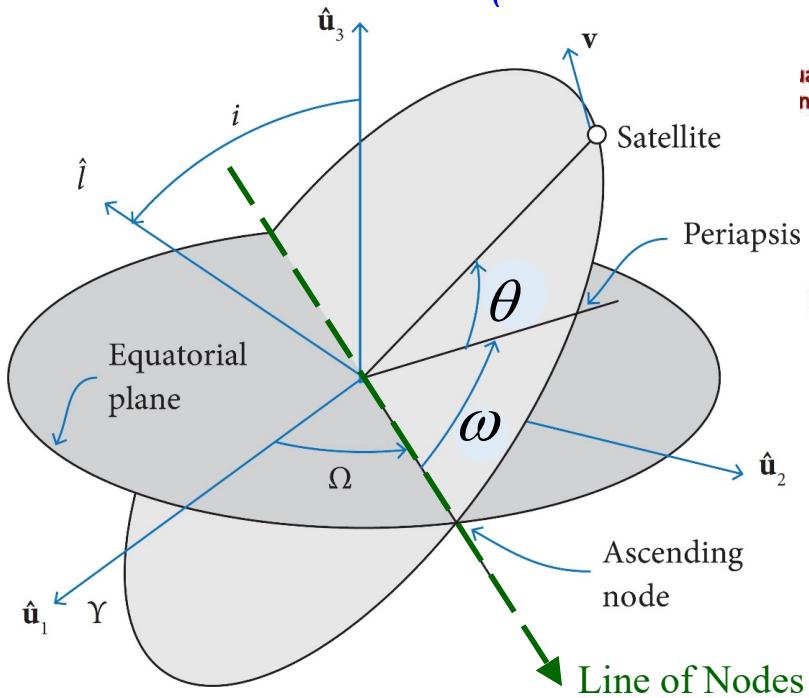

With  $P$  and  $e$  specified  $\Rightarrow r$  in polar coordinate

# Orbital Parameters ( $OP$ )

Six orbital parameters (OP) are in general needed to completely define the **orbital plane (in 3D space)** and the current position of the satellite on it.

$$OP : \{a, e, \omega, \Omega, i, M\}$$

# 2BP Properties and Motion Constants (MCs)

*Center of mass (CM) in a 2PB:*

$$\mathbf{R}_{cm} = \frac{m_1 \mathbf{R}_1 + m_2 \mathbf{R}_2}{m_1 + m_2} \Rightarrow \ddot{\mathbf{R}}_{cm} = \frac{m_1 \ddot{\mathbf{R}}_1 + m_2 \ddot{\mathbf{R}}_2}{m_1 + m_2}$$

Using the Newton's 2nd law for the two masses , we had :

$$m_1 \ddot{\mathbf{R}}_1 = \frac{G m_1 m_2 \mathbf{r}}{r^3}; \quad m_2 \ddot{\mathbf{R}}_2 = -\frac{G m_1 m_2 \mathbf{r}}{r^3} \Rightarrow \ddot{\mathbf{R}}_{cm} = 0 \rightarrow \mathbf{R}_{cm} = \mathbf{C}_1 t + \mathbf{C}_2$$

CM in 2BP does not accelerate ! so it can act as the origin of an inertial frame.

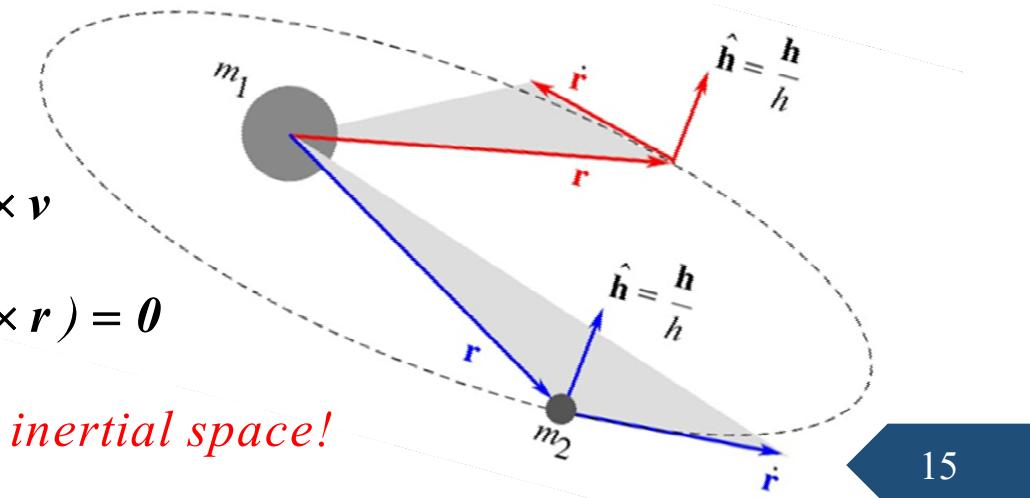

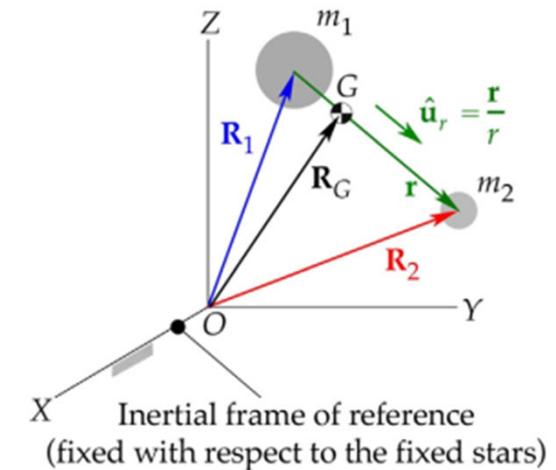

**Integrals of the motion:**

1- Angular momentum per unit mass

specific angular momentum  $\triangleq \mathbf{h} = \mathbf{r} \times \dot{\mathbf{r}} = \mathbf{r} \times \mathbf{v}$

$$\frac{d\mathbf{h}}{dt} = \dot{\mathbf{r}} \times \dot{\mathbf{r}} + \mathbf{r} \times \ddot{\mathbf{r}} = 0 + \mathbf{r} \times \left( -\frac{\mu}{r^3} \mathbf{r} \right) = -\frac{\mu}{r^3} (\mathbf{r} \times \mathbf{r}) = \mathbf{0}$$

$\mathbf{h} = \text{Constant} \Rightarrow \text{Orbital plane is fixed in the inertial space!}$

## Two Body Problem Motion Constants (MCs)

$$h = \mathbf{r} \times \mathbf{v} = r \hat{\mathbf{u}}_r \times (v_r \hat{\mathbf{u}}_r + v_{\perp} \hat{\mathbf{u}}_{\perp}) = r v_{\perp} \hat{\mathbf{h}}$$

$$v_{\perp} = v \sin \phi; v_r = v \cos \phi$$

$$v_{\perp} = v \cos \gamma; v_r = v \sin \gamma \Rightarrow \tan \gamma = \frac{v_r}{v_{\perp}}$$

$\phi$  = Zenith angle =  $(\pi/2) - \gamma$

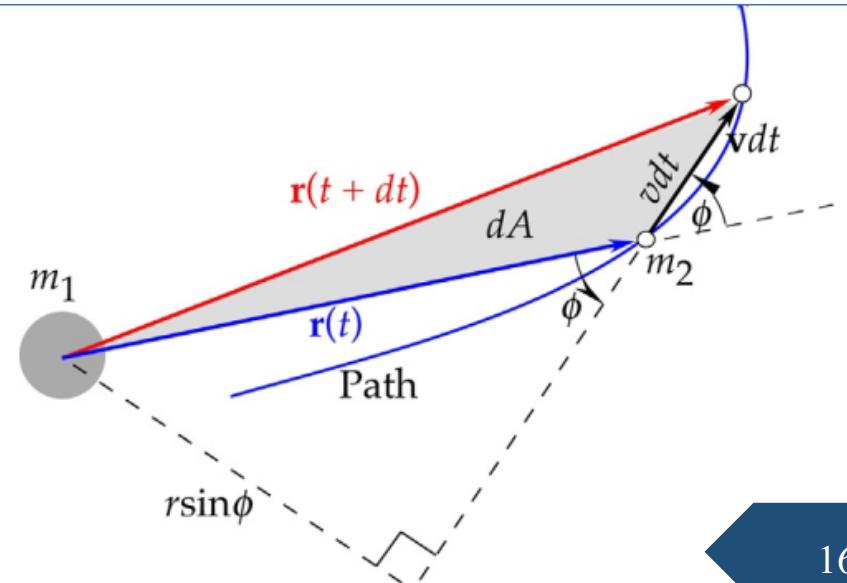

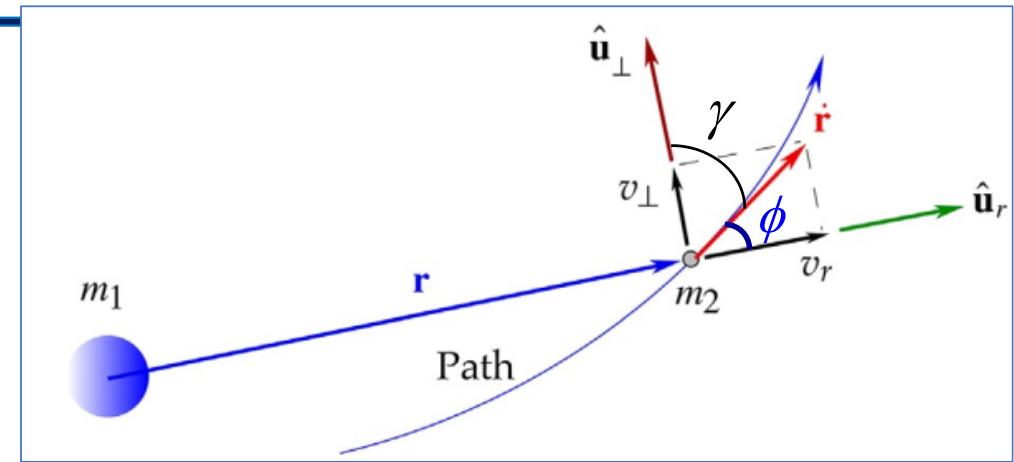

$\gamma$  = flight path angle

$$dA = \frac{1}{2} \times \text{base} \times \text{altitude}$$

$$= \frac{1}{2} \times v dt \times r \sin \phi$$

$$= \frac{1}{2} r (v \sin \phi) dt = \frac{1}{2} r v_{\perp} dt$$

$$\rightarrow \frac{dA}{dt} = \frac{h}{2} = \text{Constant!} \quad (\text{2nd Kepler's law})$$

## Two Body Problem Polar EOM (2D)

Analytic solution of 2BP

$$\ddot{\mathbf{r}} \times \mathbf{h} = -\frac{\mu}{r^3} \mathbf{r} \times \mathbf{h}$$

since  $d/dt(\dot{\mathbf{r}} \times \mathbf{h}) = \ddot{\mathbf{r}} \times \mathbf{h} + \dot{\mathbf{r}} \times \dot{\mathbf{h}}$

**Notes:**

$$A \times B \times C = B(A \cdot C) - C(A \cdot B)$$

$$\dot{\mathbf{h}} = \mathbf{0}$$

$$\mathbf{r} \cdot \dot{\mathbf{r}} = |\mathbf{r}| |\dot{\mathbf{r}}| = r \dot{r}$$

$$RHS: \frac{1}{r^3} \mathbf{r} \times \mathbf{h} = \frac{1}{r^3} [\mathbf{r} \times (\mathbf{r} \times \dot{\mathbf{r}})] = \frac{1}{r^3} [\mathbf{r}(\mathbf{r} \cdot \dot{\mathbf{r}}) - \dot{\mathbf{r}}(\mathbf{r} \cdot \mathbf{r})] = \frac{1}{r^3} [\mathbf{r}(r \dot{r}) - \dot{\mathbf{r}}(r^2)]$$

$$= \frac{1}{r^3} [\mathbf{r}(r \dot{r}) - \dot{\mathbf{r}}(r^2)] = \frac{\mathbf{r} \dot{r} - \dot{\mathbf{r}}r}{r^2}$$

$$\text{but } \frac{d}{dt} \left( \frac{\mathbf{r}}{r} \right) = \frac{r \dot{\mathbf{r}} - \mathbf{r} \dot{r}}{r^2} = -\frac{\mathbf{r} \dot{r} - r \dot{\mathbf{r}}}{r^2} \rightarrow \frac{d}{dt} (\dot{\mathbf{r}} \times \mathbf{h}) = \frac{d}{dt} \left( \mu \frac{\mathbf{r}}{r} \right) \rightarrow \frac{d}{dt} \left( \dot{\mathbf{r}} \times \mathbf{h} - \mu \frac{\mathbf{r}}{r} \right) = 0$$

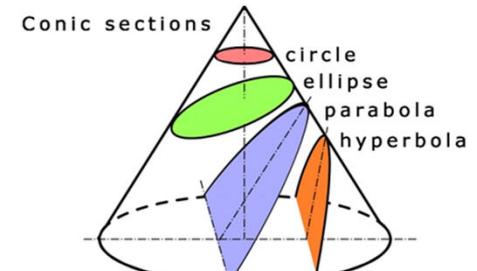

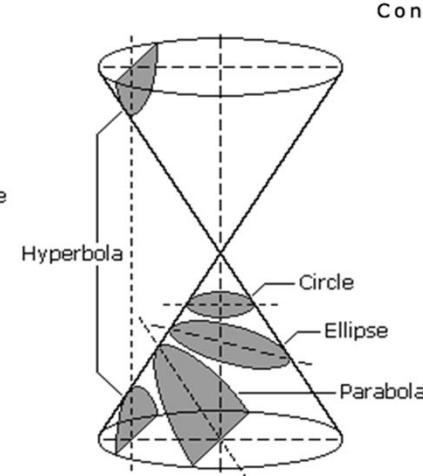

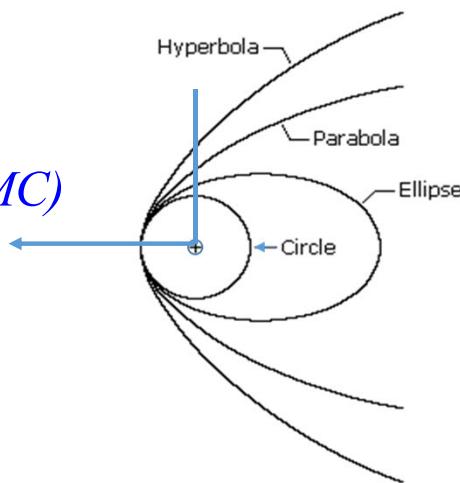

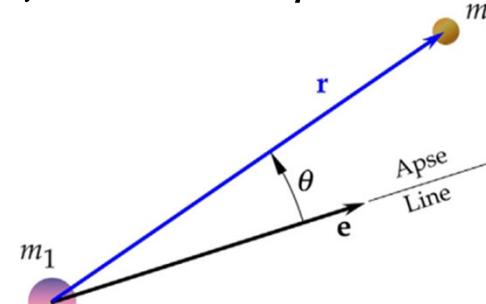

## Two Body Problem (1<sup>st</sup> Kepler's Law)

$$\begin{aligned} \frac{d}{dt} \left( \dot{\mathbf{r}} \times \mathbf{h} - \mu \frac{\mathbf{r}}{r} \right) = 0 &\rightarrow \dot{\mathbf{r}} \times \mathbf{h} - \mu \frac{\mathbf{r}}{r} = \mathbf{C} &\rightarrow \frac{\mathbf{r}}{r} + \mathbf{e} = \frac{\dot{\mathbf{r}} \times \mathbf{h}}{\mu} \xrightarrow{r} \frac{\mathbf{r} \cdot \mathbf{r}}{r} + \mathbf{r} \cdot \mathbf{e} = \frac{\mathbf{r} \cdot (\dot{\mathbf{r}} \times \mathbf{h})}{\mu} \\ &\rightarrow r + \mathbf{r} \cdot \mathbf{e} = \frac{h^2}{\mu} &\rightarrow r + r e \cos \theta = \frac{h^2}{\mu} \\ &\rightarrow r = \frac{P}{1 + e \cos \theta} \quad \text{Planar Orbit Equation} \end{aligned}$$

$p = h^2 / \mu \triangleq \text{Semi Latus Rectum}$

$\theta \equiv f \equiv v \triangleq \text{True Anomaly}$

$2 - \vec{C}/\mu = \vec{e} \equiv \text{Eccentricity Vector (MC)}$

Note: Another Vector Identity

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = (\mathbf{A} \times \mathbf{B}) \cdot \mathbf{C}$$

$$\rightarrow \mathbf{r} \cdot (\dot{\mathbf{r}} \times \mathbf{h}) = (\mathbf{r} \times \dot{\mathbf{r}}) \cdot \mathbf{h} = \mathbf{h} \cdot \mathbf{h} = h^2$$

## 2BP Geometry in Polar Coordinate System (Planar)

$$\dot{\mathbf{r}} \times \mathbf{h} - \mu \frac{\mathbf{r}}{r} = \mathbf{C} \xrightarrow{h \cdot} \mathbf{h} \cdot \mu \frac{\mathbf{r}}{r} = \mathbf{h} \cdot \mu \mathbf{e}$$

$\Rightarrow \mathbf{h} \cdot \mu \mathbf{e} = 0 \Rightarrow \mathbf{h} \perp \mathbf{e}$

$\mathbf{e}$  lies in the orbital plane

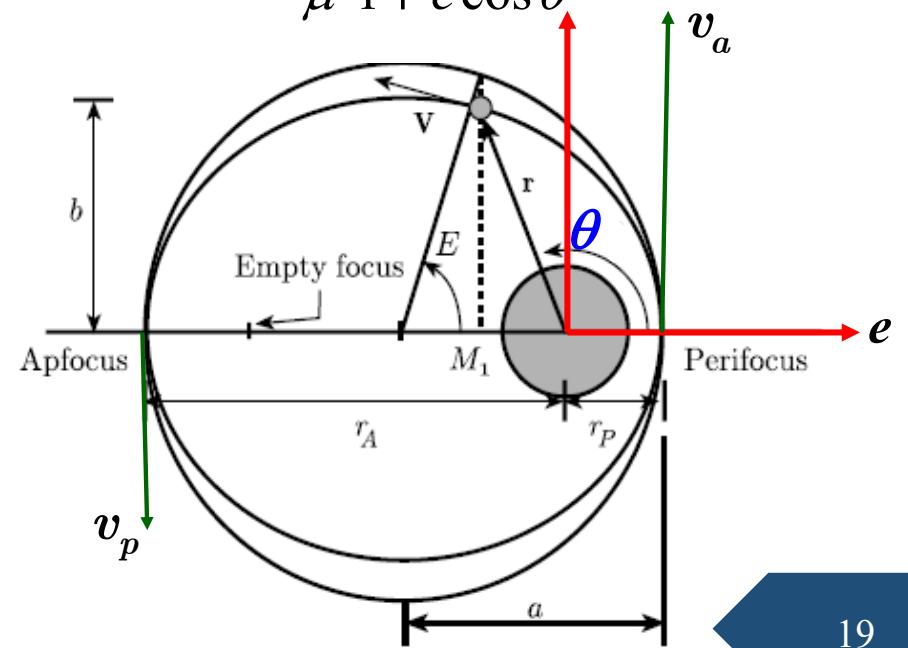

$$\mathbf{r} \cdot \mathbf{e} = r e \cos \theta \Rightarrow \cos \theta = \frac{\mathbf{r} \cdot \mathbf{e}}{r e}$$

$p = h^2 / \mu \triangleq$  Semi Latus Rectum  
 $\theta \equiv$  True Anomaly  
 $\vec{e} \equiv$  Eccentricity Vector

$$\begin{cases} \theta = 0^\circ \rightarrow r_{min} & \text{Periapsis} \\ & (\text{perigee, perihelion, ...}) \\ \theta = 180^\circ \rightarrow r_{max} & \text{Apoapsis} \\ & (\text{apogee, apohelion, ...}) \end{cases}$$

Orbit equation

$$r = \frac{h^2}{\mu} \frac{1}{1 + e \cos \theta}$$

## Two Body Problem

•  $v_{\perp} = r\dot{\theta} \rightarrow h = rv_{\perp} = r^2\dot{\theta}$

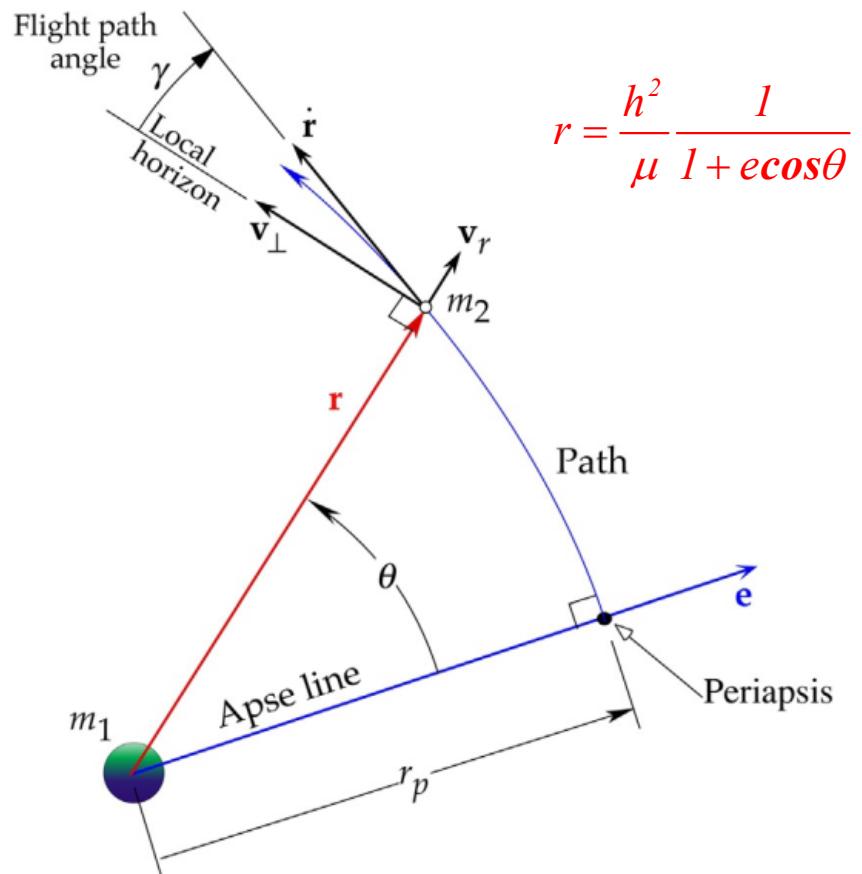

$$v_{\perp} = \frac{h}{r} = \frac{\mu}{h}(1 + e \cos \theta)$$

•  $\dot{r} = \frac{dr}{dt} = \frac{d}{dt} \left[ \frac{h^2}{\mu} \frac{1}{1 + e \cos \theta} \right]$

$$= \frac{h^2}{\mu} \left[ -\frac{e(-\dot{\theta} \sin \theta)}{(1 + e \cos \theta)^2} \right]$$

$$= \frac{h^2}{\mu} \frac{e \sin \theta}{(1 + e \cos \theta)^2} \frac{h}{r^2}$$

→  $v_r = \frac{\mu}{h} e \sin \theta$

$$\tan \gamma = \frac{v_r}{v_{\perp}} = \frac{e \sin \theta}{1 + e \cos \theta}$$

# Specific Energy Law and Conservation of Energy

- Relative linear momentum per unit mass

$$\frac{m_2 \dot{\mathbf{r}}}{m_2} = \dot{\mathbf{r}}$$

  $\ddot{\mathbf{r}} = -\frac{\mu}{r^3} \mathbf{r} \xrightarrow{\cdot \dot{\mathbf{r}}} \ddot{\mathbf{r}} \cdot \dot{\mathbf{r}} = -\mu \frac{\mathbf{r} \cdot \dot{\mathbf{r}}}{r^3}$

$$LHS: \ddot{\mathbf{r}} \cdot \dot{\mathbf{r}} = \frac{1}{2} \frac{d}{dt} (\dot{\mathbf{r}} \cdot \dot{\mathbf{r}}) = \frac{1}{2} \frac{d}{dt} (\mathbf{v} \cdot \mathbf{v}) = \frac{1}{2} \frac{d}{dt} (v^2) = \frac{d}{dt} \left( \frac{v^2}{2} \right)$$

$$RHS: \mu \frac{\mathbf{r} \cdot \dot{\mathbf{r}}}{r^3} = \mu \frac{r \dot{r}}{r^3} = \mu \frac{\dot{r}}{r^2} = -\frac{d}{dt} \left( \frac{\mu}{r} \right)$$

$$\frac{d}{dt} \left( \frac{1}{r} \right) = -\frac{1}{r^2} \frac{dr}{dt}$$

*Earth Gravitational Potential Function:  $U(r)$*

$$F_g = W = G \frac{Mm}{r^2} = m \left( \frac{GM}{r^2} \right) = mg = m \frac{\mu}{r^2}$$

$$F_g / m = \frac{\mu}{r^2} = -\nabla U \Rightarrow U = -\frac{\mu}{r}$$

$$\frac{d}{dt} \left( \frac{v^2}{2} - \frac{\mu}{r} \right) = 0$$

$\Rightarrow$  3. Specific Energy Equation for orbits (MC)

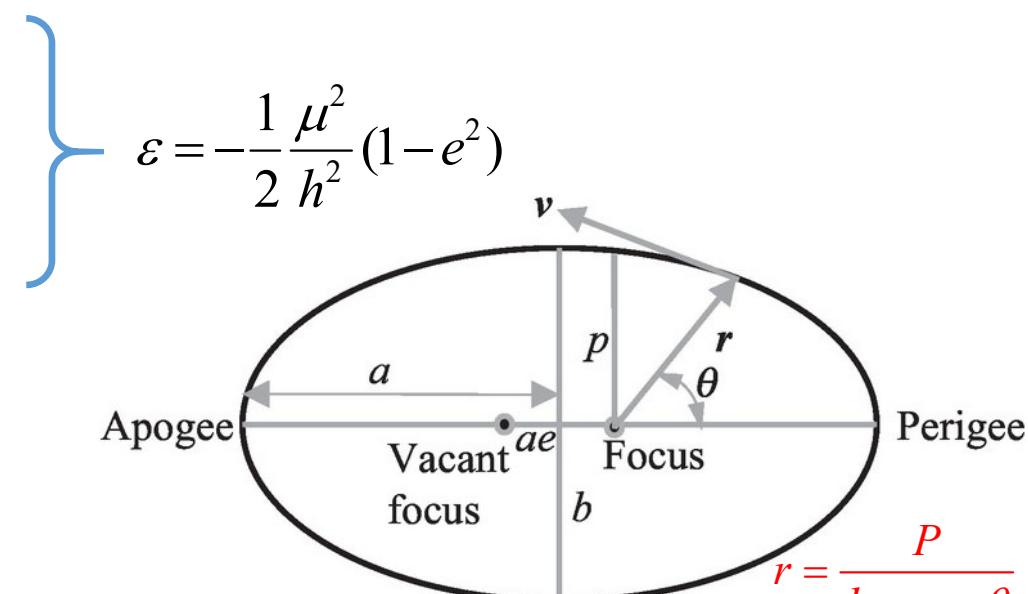

$$\frac{v^2}{2} - \frac{\mu}{r} = \varepsilon \quad (\text{constant})$$

Total Orbit Energy:  $E = m\varepsilon$

# Relation between Orbit Energy and Eccentricity (Geometry)

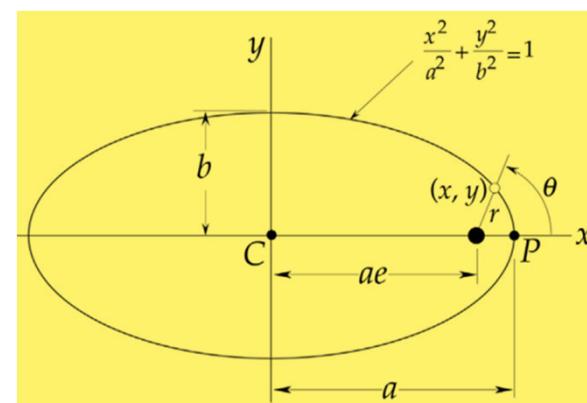

$$\varepsilon = \varepsilon_p = \frac{v_p^2}{2} - \frac{\mu}{r_p} \xrightarrow{v_p = v_{\perp} = h/r_p} \varepsilon = \frac{1}{2} \frac{h^2}{r_p^2} - \frac{\mu}{r_p}$$

Substituting for  $r_p = \frac{h^2 / \mu}{1 + e}$  and simplifying

$$r = \frac{P}{1 + e \cos \theta}$$

$e$	$\varepsilon$	Orbit Geometry
$0 < e < 1$	$\varepsilon < 0$	Circle to Ellipse
$e = 1$	$\varepsilon = 0$	Parabola
$e > 1$	$\varepsilon > 0$	Hyperbola

# 1- Circular Orbits (3<sup>rd</sup> Kepler's Law)

$$r = \frac{h^2 / \mu}{1 + e \cos \theta} \xrightarrow{e=0} r = \frac{h^2}{\mu}$$

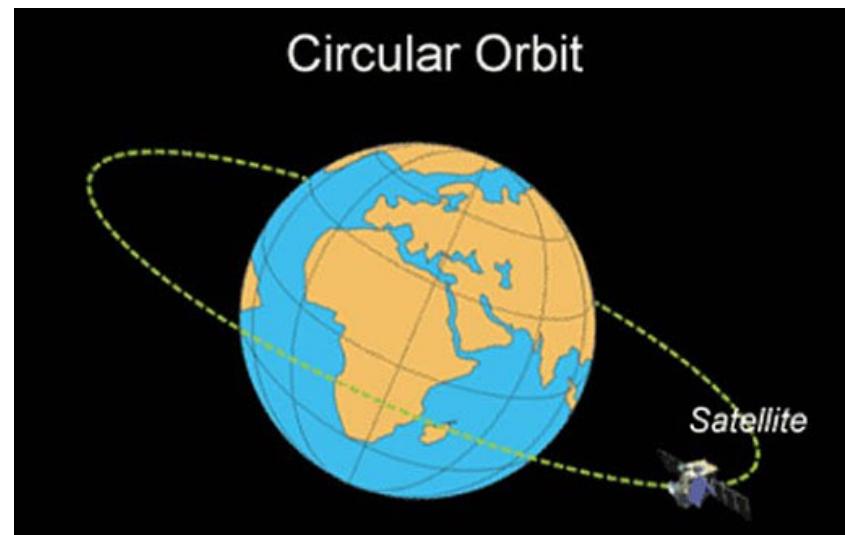

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} (1 - e^2) < 0$$

$$h = rv \rightarrow v_{circular} = v_C = \sqrt{\frac{\mu}{r}}$$

$$\frac{v^2}{2} - \frac{\mu}{r} = \varepsilon \text{ (constant)}$$

$$\text{Period } \tau = \frac{\text{circumference}}{\text{speed}} = \frac{2\pi r}{\sqrt{\mu/r}} = \frac{2\pi}{\sqrt{\mu}} r^{\frac{3}{2}} = 2\pi \sqrt{\frac{r^3}{\mu}}$$

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} = -\frac{\mu}{2r}$$

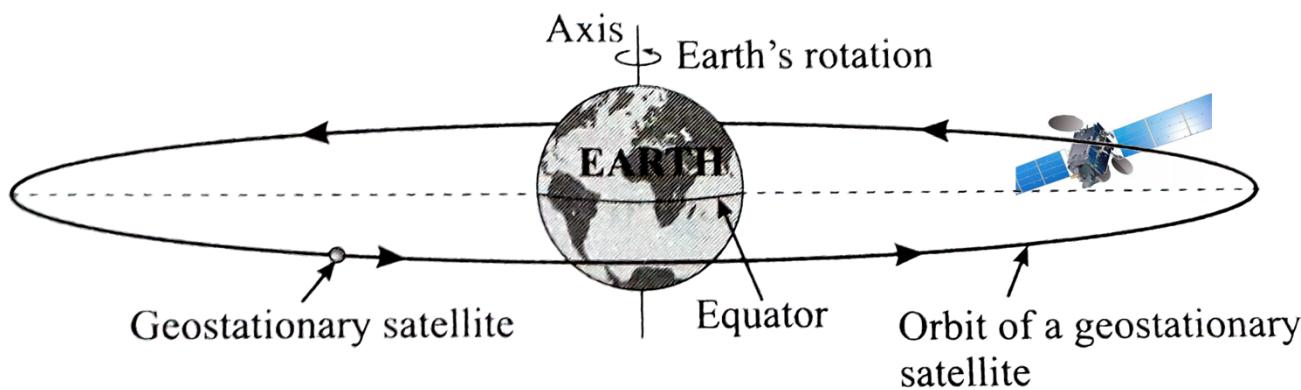

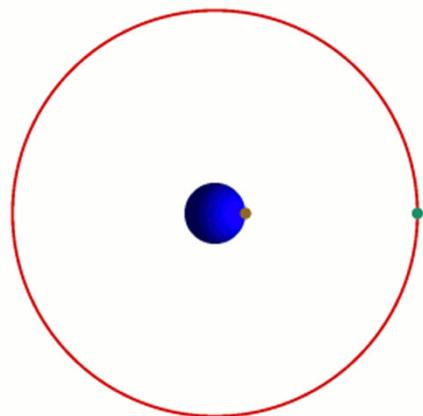

# GEO Orbits and Satellites

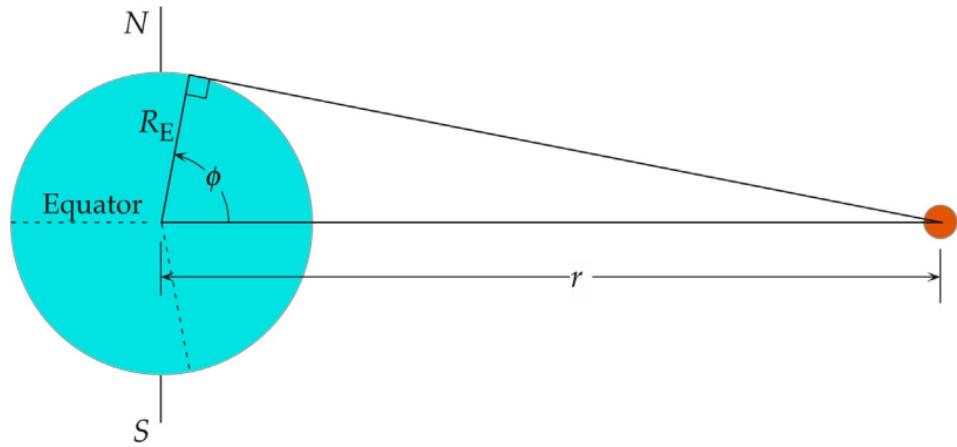

- Geostationary (Geo-Synchronous) equatorial orbits (GEO), Circular.
- Satellite angular velocity is the same as the Earth

$$\omega_E = \frac{2\pi}{24 \times 3600} \approx 7.2722 \times 10^{-5} \text{ rad/s}; \mu = 3.986 \times 10^{-5} \text{ km}^3/\text{s}^2$$

$$v_{GEO} = \sqrt{\frac{\mu}{r_{GEO}}}, \quad v_{GEO} = \omega_E r_{GEO} \rightarrow r_{GEO} = \sqrt[3]{\frac{\mu}{\omega_E^2}} = 42,164 \text{ km} \rightarrow h_{GEO} = r_{GEO} - R_E = 35768 \text{ km}$$

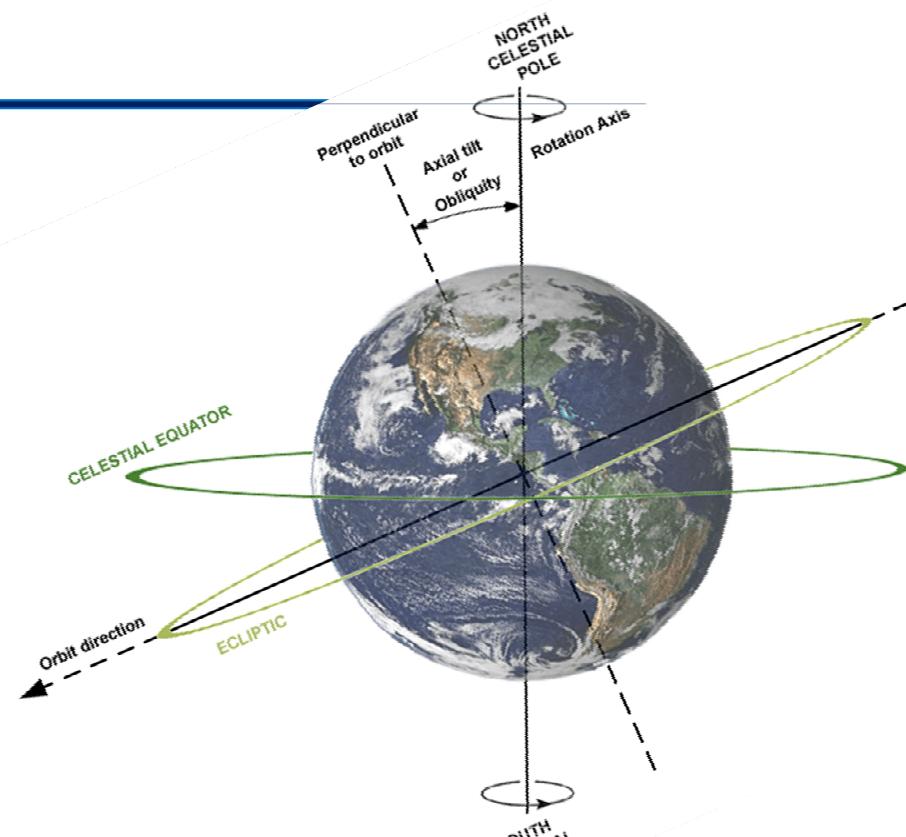

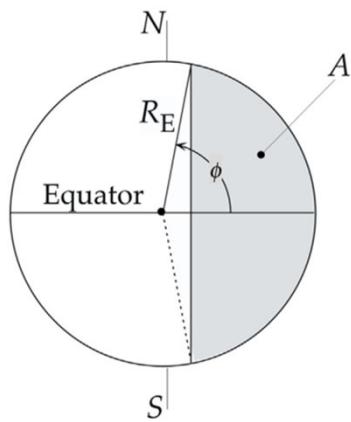

# GEO Orbit Coverage Area

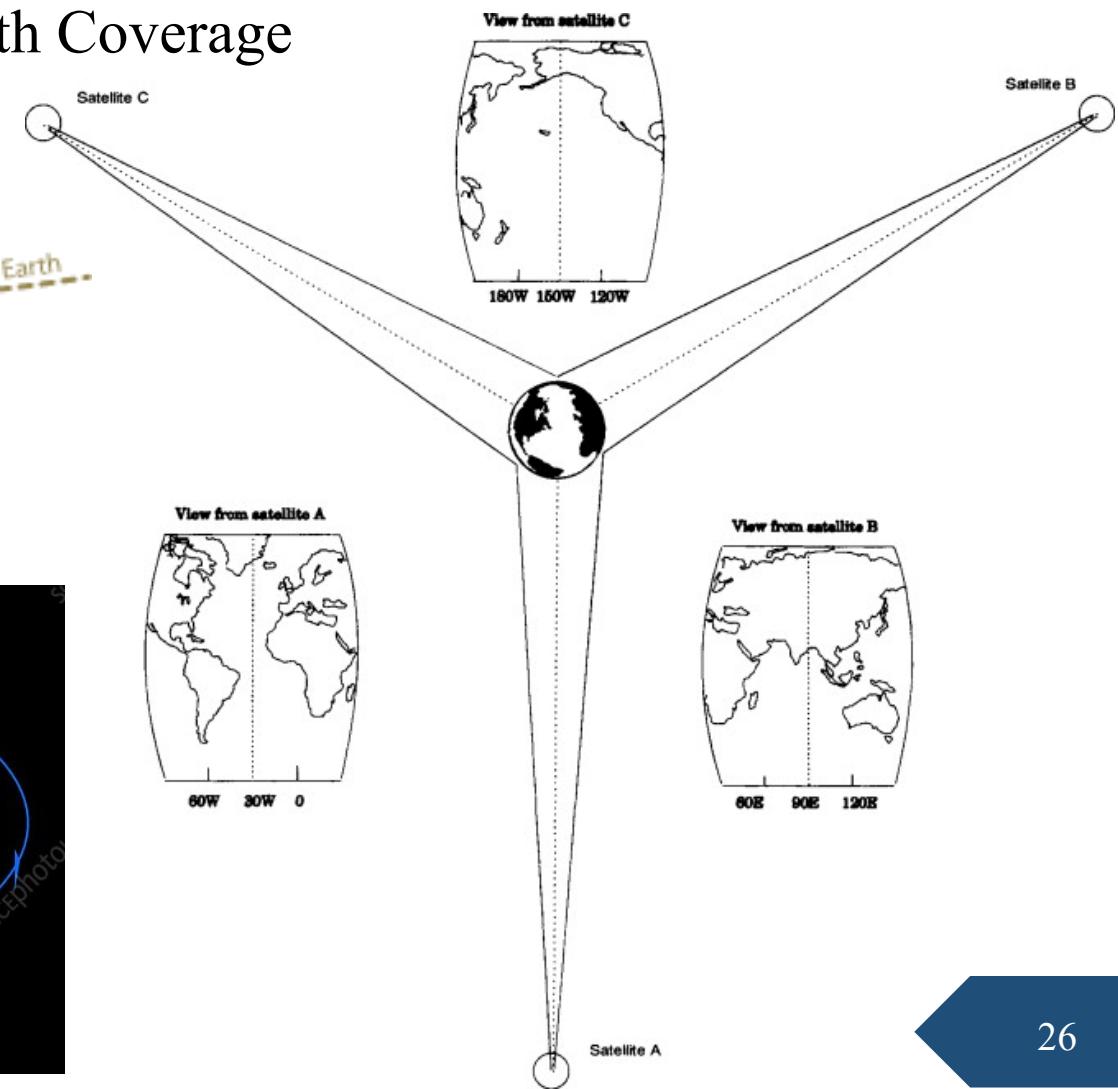

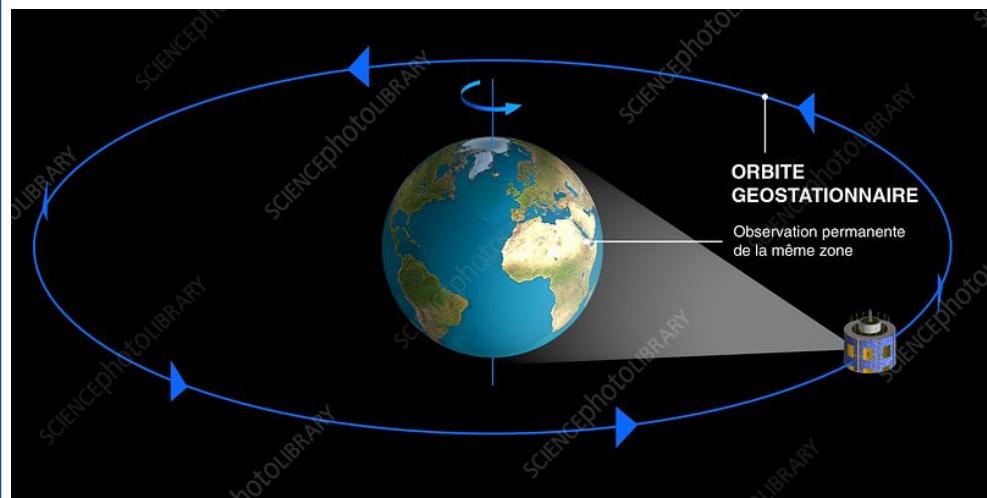

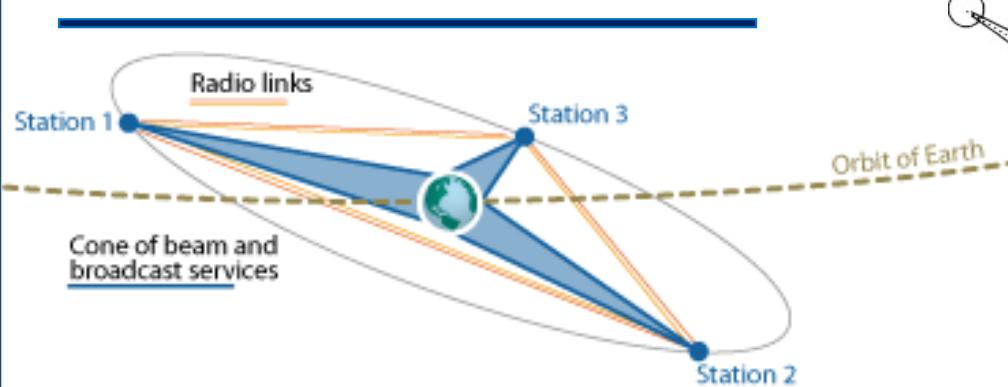

$$\varphi = \cos^{-1} \frac{R_E}{r} = \cos^{-1} \frac{6378}{42,164} = 81.30^\circ$$

$$S = 2\pi R_E^2 (1 - \cos \varphi)$$

$$\frac{S}{2\pi R_E^2} \times 100 = 84.9 \%$$

# Three GEO Satellites Give Full Earth Coverage

## 2- Elliptical Orbit in Polar Coordinates

$$0 < e < 1; \varepsilon < 0$$

$$r = \frac{h^2 / \mu}{1 + e \cos \theta} = \frac{P}{1 + e \cos \theta}$$

$$r_p = r_{\theta=0} = \frac{P}{1+e}; \quad r_a = r_{\theta=180} = \frac{P}{1-e}$$

$$2a = r_p + r_a = \frac{2P}{1-e^2} \Rightarrow P = \frac{h^2}{\mu} = a(1-e^2)$$

$$r_p = a(1-e); \quad r_a = a(1+e)$$

$$CF = C = a - FP = a - r_p = a - a(1-e) = ae$$

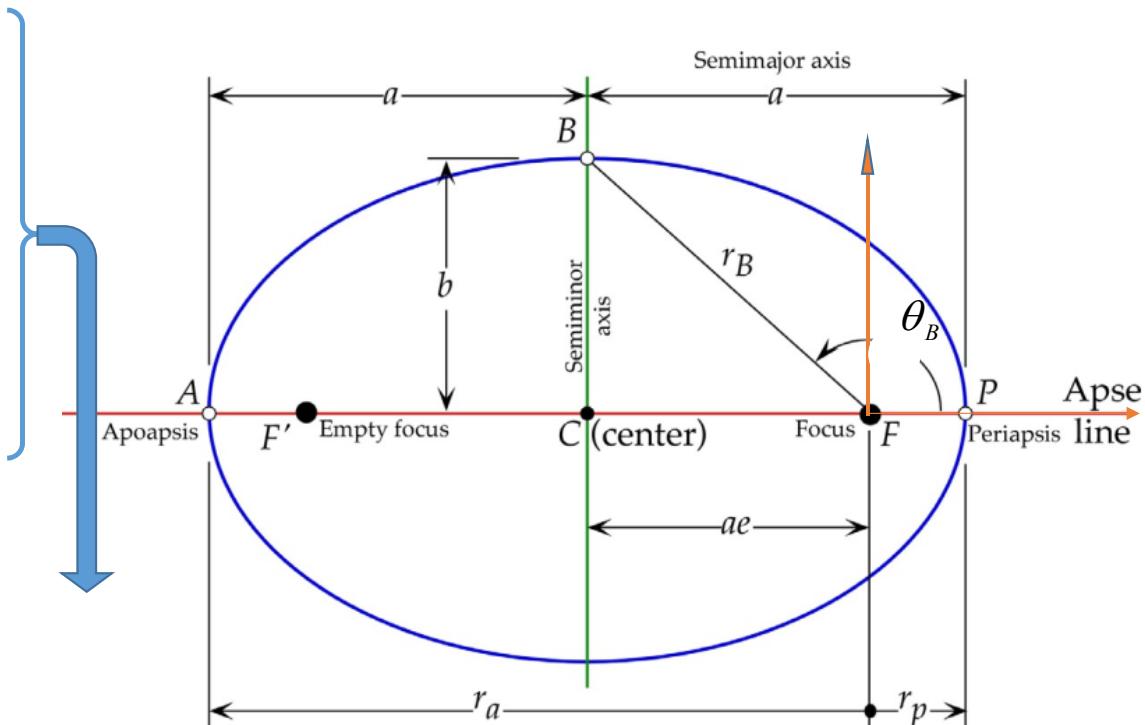

$$b^2 = a^2 - CF^2 = a^2 - a^2e^2 = a^2(1-e^2)$$

$$b = a\sqrt{1-e^2}$$

$$r_B^2 = C^2 + b^2 = (ae)^2 + a^2(1-e^2) = a^2$$

$$r_B = a \frac{1-e^2}{1+e \cos \theta_B} = a \Rightarrow 1-e^2 = 1+e \cos \theta_B$$

$$\Rightarrow \cos \theta_B = -e \rightarrow \theta_B = \cos^{-1}(-e)$$

$$r = \frac{P}{1 + e \cos \theta}$$

# Elliptical Orbits

$$0 < e < 1; \varepsilon < 0$$

- Specific energy of an elliptical orbit

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} (1 - e^2) < 0$$

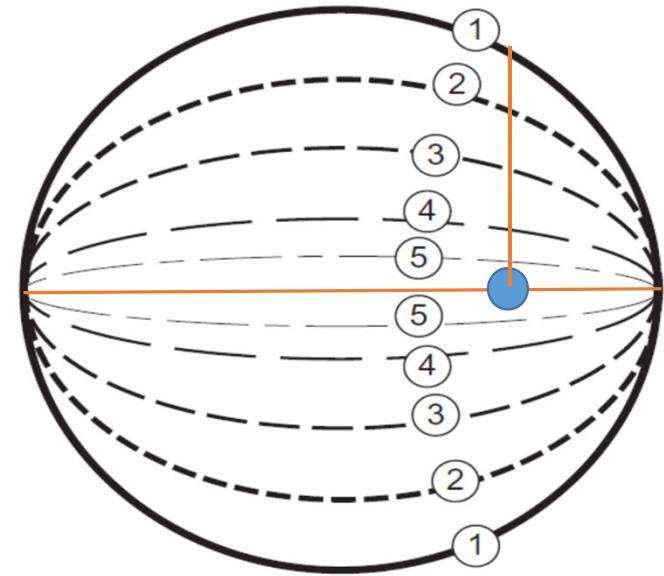

$$\varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = -\frac{\mu}{2a}$$

- Orbital Period  $\tau$

$$\frac{dA}{dt} = \frac{h}{2} \rightarrow \Delta A = \frac{h}{2} \Delta t \Rightarrow \text{For one period}$$

$$\Delta t = \tau, \Delta A = \pi ab = \frac{h}{2} \tau \Rightarrow \tau = \frac{2\pi ab}{h}$$

$$\tau = \frac{2\pi}{h} a^2 \sqrt{1 - e^2} = \frac{2\pi}{\sqrt{\mu a(1 - e^2)}} a^2 \sqrt{1 - e^2} = 2\pi \sqrt{\frac{a^3}{\mu}}$$

$$\tau = 2\pi \sqrt{\frac{a^3}{\mu}}$$

# Example 1

A meteorite has been spotted to approach the Earth at an **altitude** of 37000 km with a speed of 8 km/s. if at the time of initial observation its flight path is -65 degrees, investigate the possibility of its encounter with the Earth or the closest approach (pass) distance.

**Other related questions:** Where does it hit the Earth (2D,3D)?

When will it hit the Earth?

$$\varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = 22.81 > 0 \Rightarrow \text{Hyperbolic Trajectory}$$

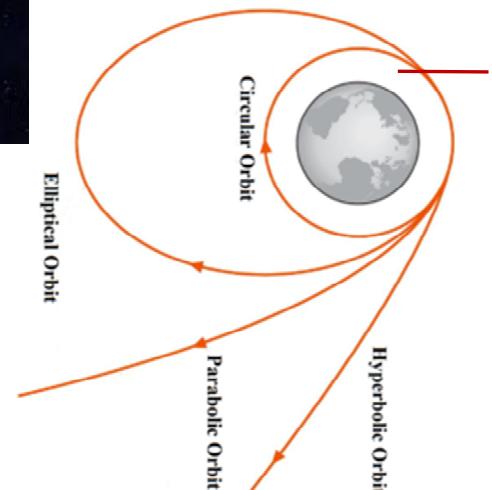

$$h = rv \cos \gamma = 1.467e + 5 \text{ km}^2 / s$$

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} (1 - e^2) \Rightarrow e = 2.678; P = \frac{h^2}{\mu} = 53961$$

$$r_p = P / (1 + e) = 14671.2 > R_E \Rightarrow \text{No Encounter!}$$

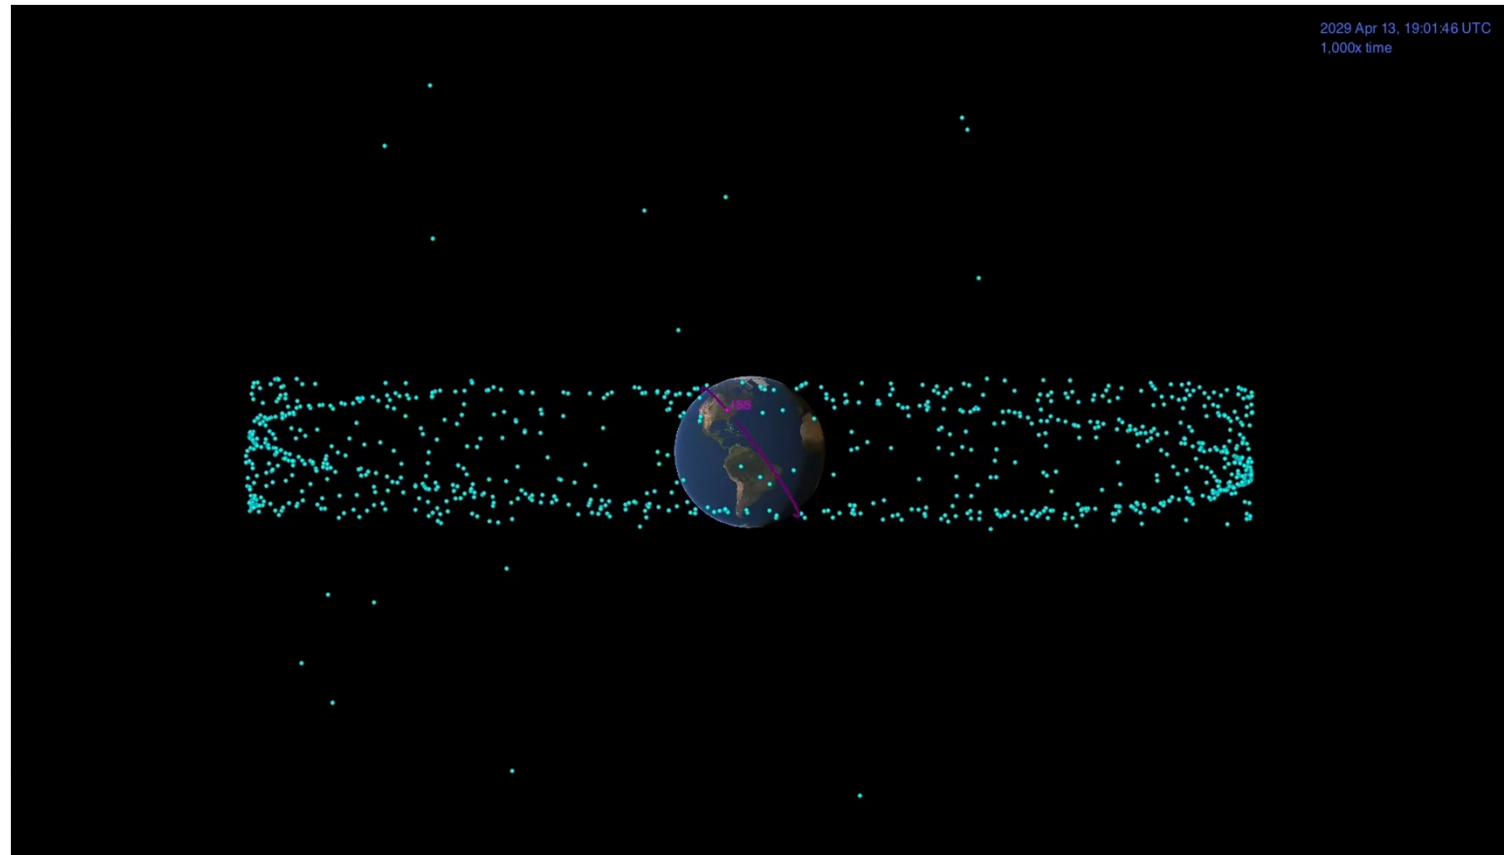

$$\text{Closest Approach} = r_p - R_E = 5605 \text{ km}$$

$$r = \frac{53961}{1 + 2.678 \cos \theta}$$

# Potential Asteroid Hazards

Animation shows **Apophis' 2029** path compared to the swarm of satellites orbiting Earth.

## Example 2

An Earth satellite has a perigee **altitude** of 6.22 km with a **maximum velocity** of 8.6038 km/s. Find the orbital period and velocity of satellite when the true anomaly is 120 degrees.

$$a) \varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = -\frac{\mu}{2a}$$

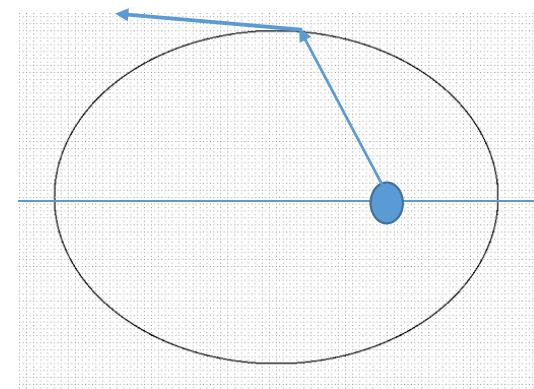

$$\frac{8.6038^2}{2} - \frac{398600}{6378 + 6.22} = -\frac{\mu}{2a} \rightarrow a = 7839.5 \text{ km}$$

$$\tau = 2\pi \sqrt{\frac{a^3}{\mu}} = 6907.9 \text{ sec} = 1.91 \text{ hr}$$

$$b) r = \frac{h^2 / \mu}{1 + e \cos \theta}, \quad h = r_p v_p = 5.4929e+04 \Rightarrow h^2 = \mu P = \mu a(1 - e^2) \rightarrow e = 0.18$$

$$r_{\theta=120} = \frac{h^2 / \mu}{1 + 0.18 \cos 120} = 8343.6 \text{ km}$$

$$\varepsilon = \frac{v_{\theta=120}^2}{2} - \frac{\mu}{r_{\theta=120}} \rightarrow v_{\theta=120} = 6.6859 \text{ km / s}$$

### 3- Parabolic Trajectory

$$e = 1; \varepsilon = 0$$

Parabolic orbits are not usually observed in nature! They are however important as the boundary between open and closed orbits.

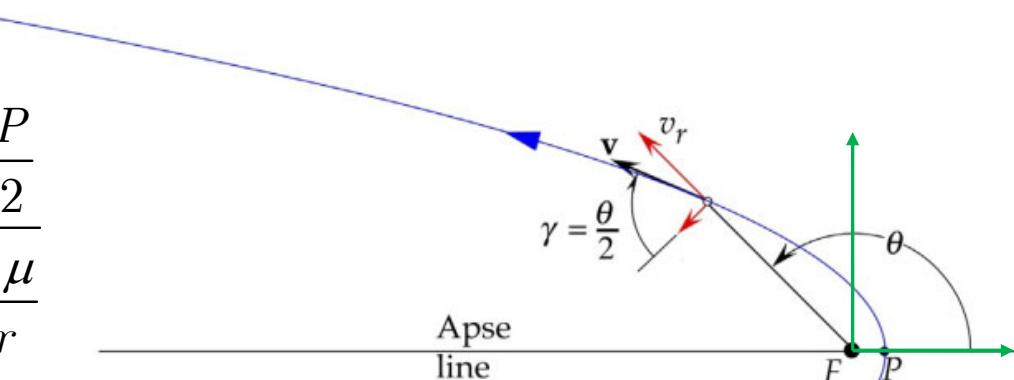

$$r = \frac{h^2}{\mu} \frac{1}{1 + \cos \theta}; \quad \theta = \pi \rightarrow r \rightarrow \infty; \quad \theta = 0 : r_p = \frac{P}{2}$$

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} (1 - e^2) \xrightarrow{e=1} \frac{v^2}{2} - \frac{\mu}{r} = 0 \Rightarrow v = \sqrt{\frac{2\mu}{r}}$$

$$\Rightarrow \text{Escape Velocity} = v_{ESC} = \sqrt{\frac{2\mu}{r}} = \sqrt{2}v_c$$

$$\tan \gamma = \frac{v_r}{v_\perp} = \frac{e \sin \theta}{1 + e \cos \theta}$$

$$\tan \gamma = \frac{\sin \theta}{1 + \cos \theta} = \frac{2 \sin \frac{\theta}{2} \cos \frac{\theta}{2}}{2 \cos^2 \frac{\theta}{2}} = \frac{\sin \frac{\theta}{2}}{\cos \frac{\theta}{2}} = \tan \frac{\theta}{2} \Rightarrow \gamma = \frac{\theta}{2}$$

## 4- Hyperbolic Trajectory

$$e > 1; \varepsilon > 0$$

Meteorite and asteroids are usually on a hyperbolic path. Hyperbolic trajectories (HT) are also utilized for interplanetary missions due to their positive specific energy.

Net effect of a HT flyby will be a change in the velocity direction denoted by an angle  $\delta$ , which is the angle between the asymptotes! Other HT properties are as follows:

1. *Asymptotes* (defined for  $r \rightarrow \infty$ )

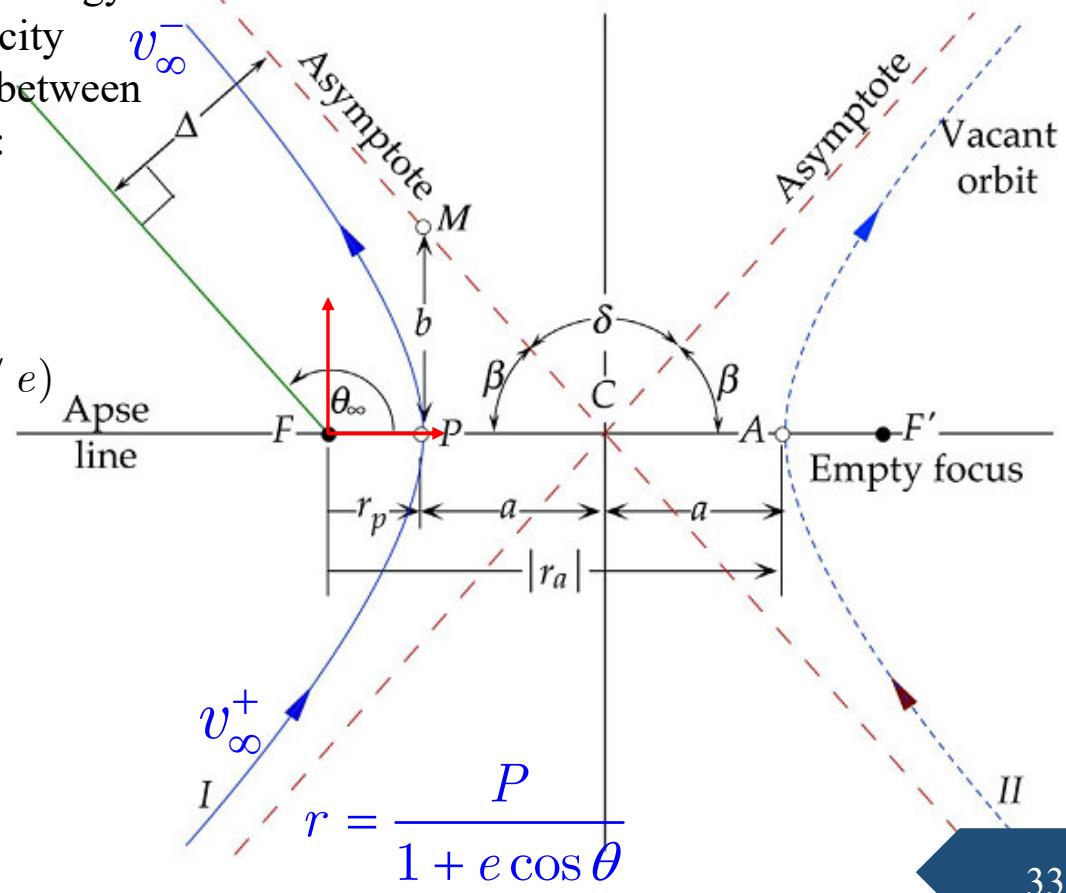

$$1 + e \cos \theta = 0 \rightarrow \theta_\infty = \cos^{-1}(-1/e)$$

$$\cos(\pi - \theta_\infty) = -\cos \theta_\infty = \cos \beta \Rightarrow \beta = \cos^{-1}(1/e)$$

2. *Excess Hyperbolic velocity*

$$\varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = \text{constant} = \frac{v_\infty^2}{2} - \frac{\mu}{r_\infty} = -\frac{\mu}{2a}$$

$$\rightarrow v_\infty^+ = v_\infty^- = \sqrt{-\frac{\mu}{2a}}$$

# Hyperbolic Trajectory

$$e > 1; \varepsilon > 0$$

## 3. Turn angle $\delta$ , and Aiming Distance $\Delta$

$$\frac{\pi}{2} - \frac{\delta}{2} = \pi - \theta_\infty \Rightarrow \theta_\infty = \frac{\pi}{2} + \frac{\delta}{2}$$

$$\cos \theta_\infty = -\sin(\frac{\delta}{2}) \Rightarrow \sin(\frac{\delta}{2}) = 1/e$$

$$\rightarrow \delta = 2 \sin^{-1}(1/e)$$

Aiming Distance  $\Delta$  : a design/control parameter for interplanetary missions

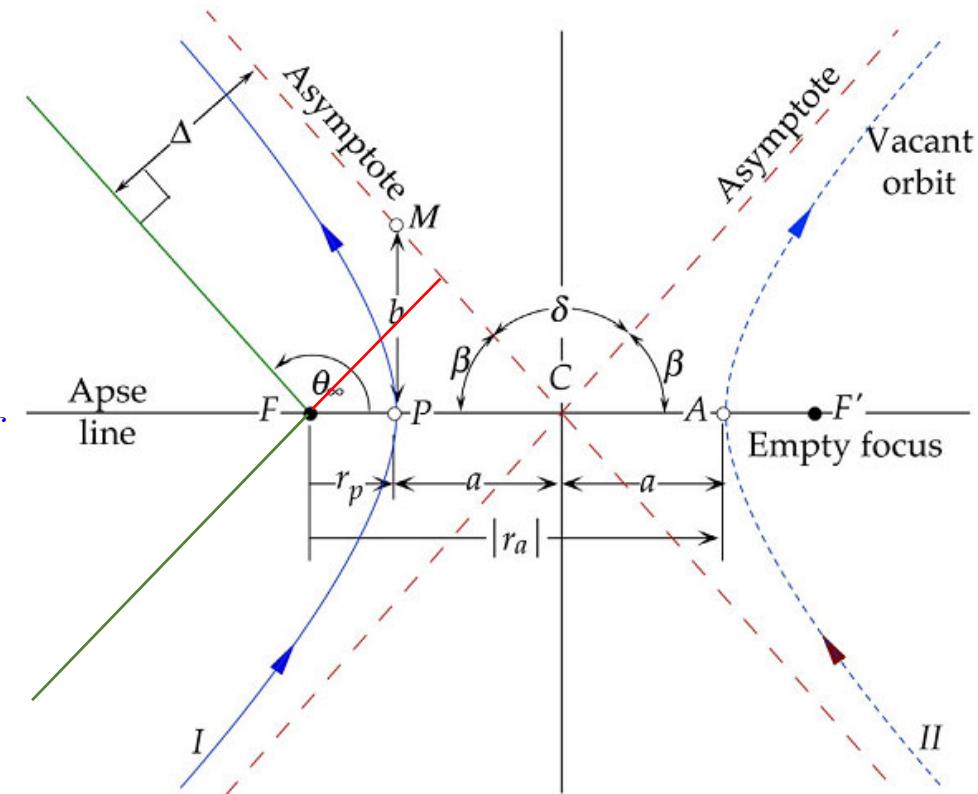

$$|\vec{v}_\infty^+| = |\vec{v}_\infty^-| = v_\infty$$

$$h = v_\infty \Delta \Rightarrow \Delta = h / v_\infty$$

Or

$$\Delta = (r_p + a) \sin \beta = CF \sin \beta = C \sin \beta = ae \sin \beta$$

$$\Delta = ae \frac{\sqrt{e^2 - 1}}{e} = a\sqrt{e^2 - 1} = b$$

$$\varepsilon = -\frac{\mu}{2a} > 0 \Rightarrow a < 0$$

## Example 3

Determine the true anomaly of the meteorite at the instant of observation.

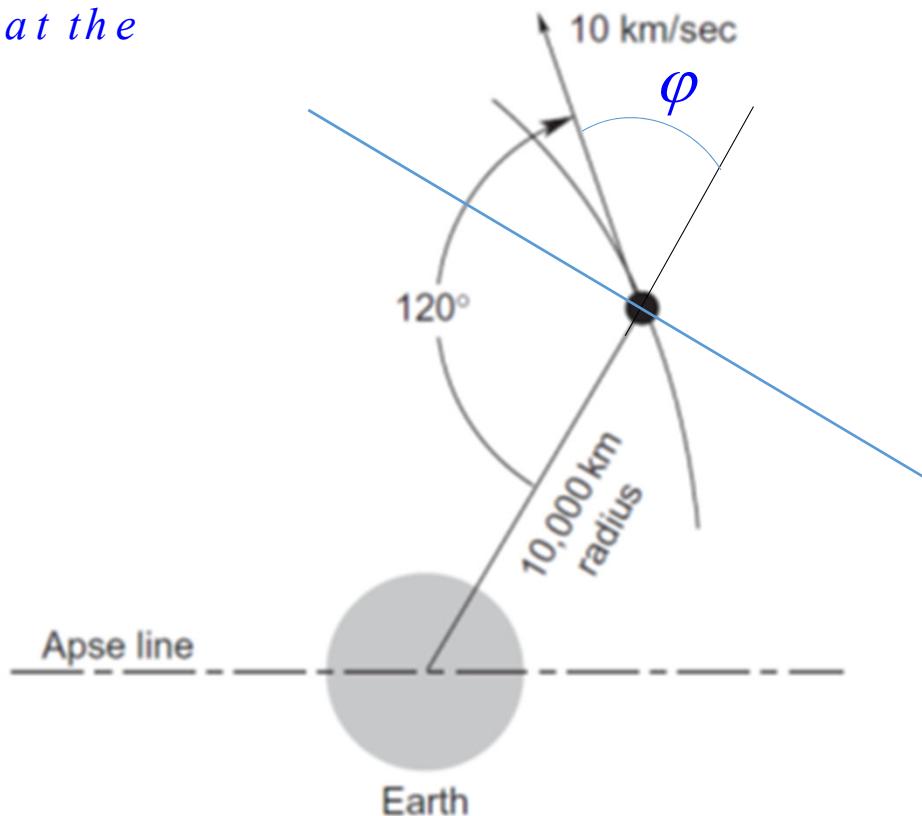

$$\frac{v^2}{2} - \frac{\mu}{r} = 10.14 > 0 \rightarrow \text{Hyperbolic Orbit}$$

$$\varepsilon = -\frac{\mu}{2a} \rightarrow a = -19655 \text{ km}$$

$$h = rv \sin \varphi = rv \sin(\pi - 120^\circ) = 86603 \text{ km}^2 / s$$

$$\frac{h^2}{\mu} = a(1 - e^2) \rightarrow e = 1.39$$

$$r = \frac{a(1 - e^2)}{1 + e \cos \theta} \rightarrow \theta \approx 51 \text{ deg}$$

# Astronomical/Canonical Units

As the mass and distances of celestial bodies are not exact and dealing with large numbers are difficult, **Astronomical** or **canonical** units are sometimes utilized to describe interplanetary motion:

## A : for Planets around the Sun

1. **Distance Unit** :  $1AU = 149\ 597\ 870.691\ km \approx 150e+6\ km$

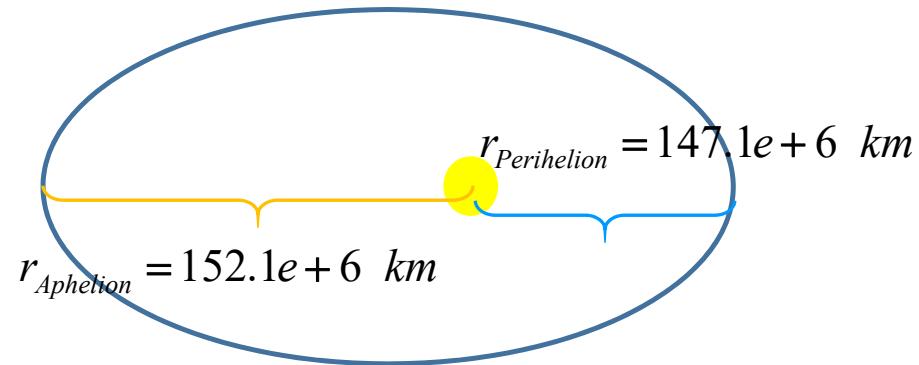

### Examples:

$$Sun - Venus \text{ distance} = 108.2e+6\ km = 0.72\ AU$$

$$Sun - Mars \text{ distance} = 227.9e+6\ km = 1.52\ AU$$

2. **Time unit (TU)** is defined based on one orbital revolution ( $2\pi$ ) of the Earth around the Sun.

$$1\ TU = 2\pi \sqrt{\frac{a_{Sun-Earth}^3}{\mu_{Sun}}} = 31.685e+6\ Sec$$

Standard gravitational parameter  $\mu = G M$  (mass of the celestial body )

Celestial Body	$\mu [\text{km}^3 \text{s}^{-2}]$
<u>Sun</u>	$1.32712440018 \times 10^{11}$
<u>Mercury</u>	$2.2032 \times 10^4$
<u>Venus</u>	$3.24859 \times 10^5$
<u>Earth</u>	$3.986004418 \times 10^5$
<u>Moon</u>	$4.9048695 \times 10^3$
<u>Mars</u>	$4.282837 \times 10^4$
<u>Ceres</u>	$6.26325 \times 10$
<u>Jupiter</u>	$1.26686534 \times 10^8$
<u>Saturn</u>	$3.7931187 \times 10^7$
<u>Uranus</u>	$5.793939 \times 10^6$
<u>Neptune</u>	$6.836529 \times 10^6$
<u>Pluto</u>	$8.71 \times 10^2$
<u>Eris</u>	$1.108 \times 10^3$

# Astronomical/Canonical Units

---

## B : for Orbits around the Earth or Planets

1. 1 Distance Unit is defined as the radius of the Celestial body under study.
  2. Time unit (TU) is defined such that circular velocity of the satellite around the celestial body will be equal to 1 DU/TU . In this sense, the planet gravity constant will be,  $\mu = 1$  since the circular velocity is :  $v_c = \sqrt{\mu / r}$
- ⌚ Example for an Earth orbiting Satellites:

$$1 DU = 6378.137 \text{ km}; \mu = 1$$

$$\tau = 2\pi \sqrt{\frac{r^3}{\mu}} \Rightarrow \tau = 2\pi ; 1 TU = 2\pi \sqrt{\frac{1 DU^3}{\mu}}$$

$$So, 1 TU = 2\pi \sqrt{\frac{6378.137^3}{398600}} \text{ sec} \rightarrow 1 TU \approx 806.8 \text{ sec} \approx 13.44 \text{ min}$$

## Example 4

---

The instantaneous position and velocity of an Earth orbiting satellite with respect to the ECI is provided below in Astronomical units.

- 1- Find the satellite period.
- 2- The satellite position after 30 degrees increase in its true anomaly.

1.

$$\vec{r}(t_0) = [1.1, 0, 0]^T \text{DU} \Rightarrow r = 1.1 \text{ DU}$$

$$\vec{v}(t_0) = [0.9, 0.9, 0]^T \text{DU / TU} \Rightarrow v = 1.2728 \text{ DU / TU}$$

$$\frac{v^2}{2} - \frac{\mu}{r} = -\frac{\mu}{2a} \rightarrow \frac{1.2728^2}{2} - \frac{1}{1.1} = -0.09909 = -\frac{\mu}{2a} \Rightarrow a = 5.0459 \text{ DU}$$

$$\tau = 2\pi \sqrt{\frac{a^3}{\mu}} = 2\pi \sqrt{\frac{5.0459^3}{\mu}} = 71.2171 \text{ TU} = 5.7459e+04 \text{ sec}$$

## Example 4 Continued

---

2.

$$h = \text{norm}(\mathbf{r}_0 \times \mathbf{v}_0) = 0.99 \text{ DU}^2 / \text{TU} \Rightarrow P\mu = h^2 \Rightarrow P = 0.9801 \text{ DU}$$

$$P = a(1 - e^2) \Rightarrow e = 0.8976$$

$$r = \frac{h^2}{\mu} \frac{1}{1 + e \cos \theta} = 1.1 \Rightarrow \theta = 96.975 \text{ at current position}$$

$$r = \frac{h^2}{\mu} \frac{1}{1 + e \cos(\theta + 30)} = 2.13 \text{ DU}$$

$$\text{Altitude} = r - R_E = 1.1302 \text{ DU} = 7,208.4 \text{ km}$$

# General Orbit Time Relation (GOTR)

Orbital time is related to SC position in orbit :

- 1- The direct problem : Given an orbital position, find the time elapsed since Periapsis.
- 2- The indirect problem : Given time elapsed since Periapsis, find SC position.

*Recall:*  $h = r v \sin \phi = r v \cos \gamma = r v_{\perp}$ , But  $v_{\perp} = r \dot{\theta} \rightarrow h = r^2 \dot{\theta}$

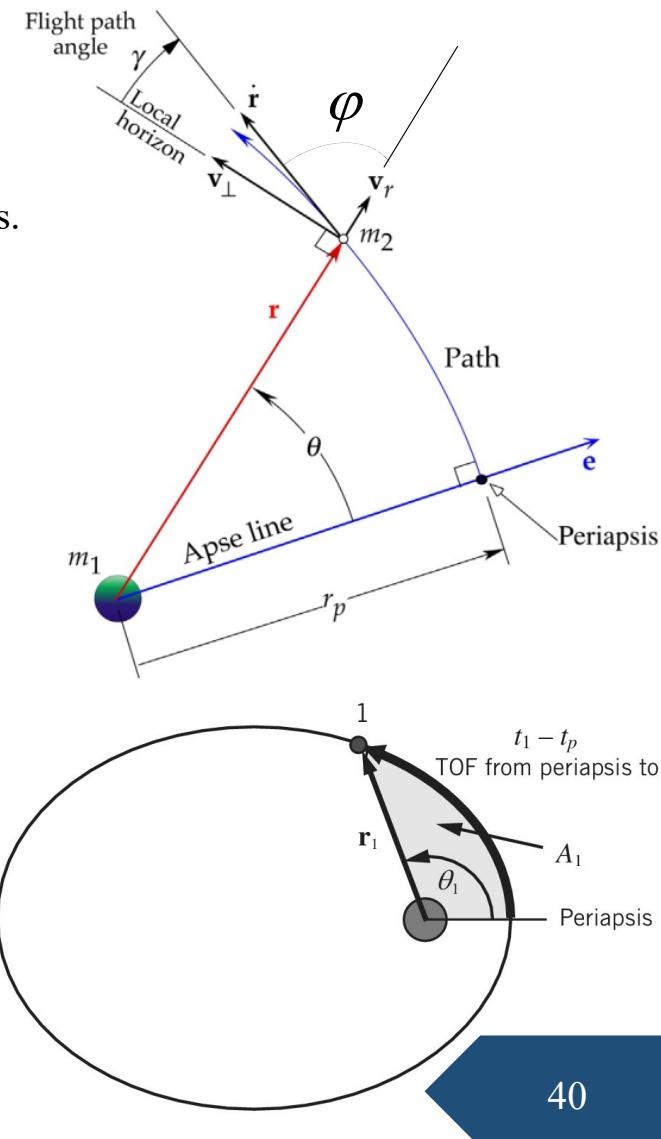

$$\frac{d\theta}{dt} = \frac{h}{r^2} \Rightarrow dt = \frac{r^2}{h} d\theta; \text{ and since } r = \frac{h^2 / \mu}{1 + e \cos \theta}$$

$$dt = \frac{h^3 / \mu^2}{(1 + e \cos \theta)^2} d\theta \Rightarrow \frac{\mu^2}{h^3} \int_{t_0}^t dt = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2}$$

$$\frac{\mu^2}{h^3} (t - t_p) = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2}$$

$t_p$  = time at periapsis passage ( $\theta=0$ ), is usually assumed 0. So:  
*t* is the time from perapsis passage using the following GOTR,

$$\text{General Orbit Time Relation : } \frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2}$$

# Some Mathematical Relations for Integration of GOTR

---

$$\frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1+e \cos \theta)^2} = ?$$

$$\int \frac{dx}{(a+b \cos x)^2} = \frac{1}{(a^2 - b^2)^{3/2}} \left( 2a \tan^{-1} \sqrt{\frac{a-b}{a+b}} \tan \frac{x}{2} - \frac{b \sqrt{a^2 - b^2} \sin x}{a + b \cos x} \right) \quad (b < a)$$

$$\int \frac{dx}{(a+b \cos x)^2} = \frac{1}{a^2} \left( \frac{1}{2} \tan \frac{x}{2} + \frac{1}{6} \tan^3 \frac{x}{2} \right) \quad (b = a)$$

$$\int \frac{dx}{(a+b \cos x)^2} = \frac{1}{(b^2 - a^2)^{3/2}} \left( \frac{b \sqrt{b^2 - a^2} \sin x}{a + b \cos x} - a \ln \left( \frac{\sqrt{b+a} + \sqrt{b-a} \tan(x/2)}{\sqrt{b+a} - \sqrt{b-a} \tan(x/2)} \right) \right) \quad (b > a)$$

# Application of GOTR to Circular and Elliptic Orbits

---

## 1- Circular Orbits

$$\frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2}, \quad e = 0 \rightarrow \frac{\mu^2}{h^3} t = \int_0^\theta d\theta$$

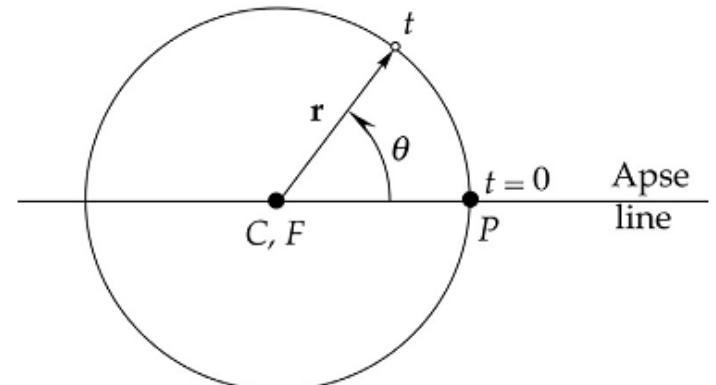

$$t = \frac{h^3}{\mu^2} \theta, \quad \text{But: } r = h^2 / \mu \rightarrow h^3 = r^{3/2} \mu^{3/2}$$

$$\rightarrow t = \frac{r^{3/2}}{\sqrt{\mu}} \theta$$

$$\text{Note: } \tau = 2\pi \sqrt{\frac{a^3}{\mu}} \Rightarrow \frac{r^{3/2}}{\sqrt{\mu}} = \frac{\tau}{2\pi}$$

$$\rightarrow t = \frac{\tau}{2\pi} \theta \Rightarrow \text{inverse relation: } \theta = \frac{2\pi}{\tau} t$$

$$n = \text{Mean Motion} = \frac{2\pi}{\tau} \Rightarrow \theta = nt$$

# Application of GOTR to Circular and Elliptic Orbits

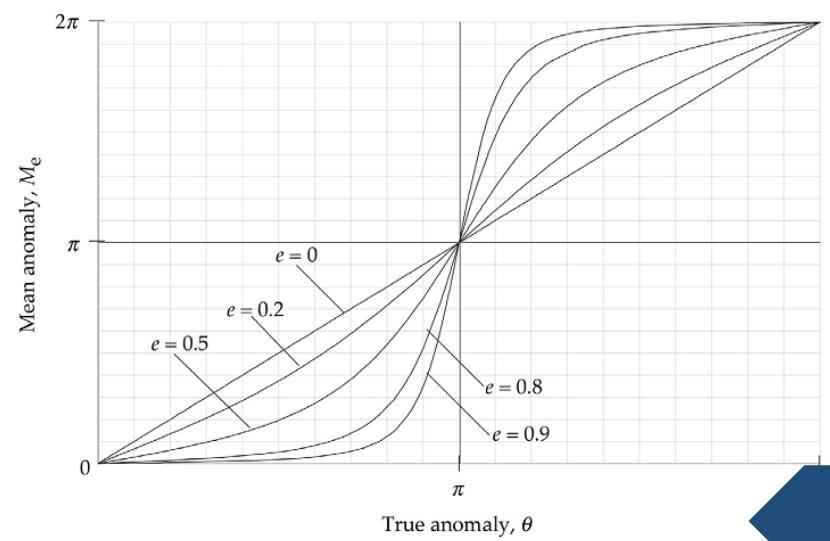

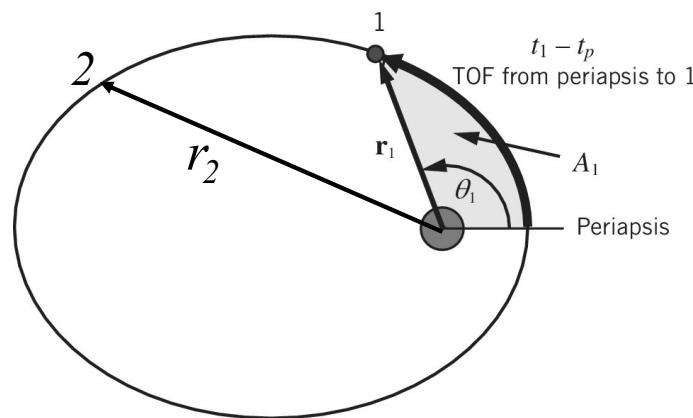

## 2(a) - Elliptical Orbits time via Elliptical Mean Anomaly(EMA)

$$\frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2} = \frac{1}{(1 - e^2)^{3/2}} \left( 2 \tan^{-1} \sqrt{\frac{1 - e}{1 + e}} \tan \frac{\theta}{2} - \frac{e \sqrt{1 - e^2} \sin \theta}{1 + e \cos \theta} \right)$$

Let  $M_e = \left( 2 \tan^{-1} \sqrt{\frac{1 - e}{1 + e}} \tan \frac{\theta}{2} - \frac{e \sqrt{1 - e^2} \sin \theta}{1 + e \cos \theta} \right) \equiv f(\theta, e) = \text{Elliptical Mean Anomaly(EMA)}$

$$\Rightarrow M_e = \frac{\mu^2}{h^3} (1 - e^2)^{3/2} t_p$$

$$\text{Or : } \Delta M_e = \frac{\mu^2}{h^3} (1 - e^2)^{3/2} \Delta t$$

# Elliptical Orbits $(0 < e < 1)$

2(b)- Elliptical Orbits time via utility of mean motion

$$\frac{h^2}{\mu} = a(1 - e^2) \rightarrow \left[ \frac{h^2}{\mu} \right]^{\frac{3}{2}} = \left[ a(1 - e^2) \right]^{\frac{3}{2}} \rightarrow h^3 = \left[ \mu a(1 - e^2) \right]^{\frac{3}{2}}$$

$$M_e = \frac{\mu^2}{h^3} (1 - e^2)^{3/2} t_P = \frac{\mu^2}{\left[ \mu a(1 - e^2) \right]^{\frac{3}{2}}} (1 - e^2)^{3/2} t_P = \frac{\mu^{\frac{1}{2}}}{a^{\frac{3}{2}}} t = \frac{2\pi}{\tau} t = nt_P$$

$$\Delta M_e = n \Delta t$$

2(c)- Elliptical Orbits time (c) via utility of Eccentric anomaly (E)

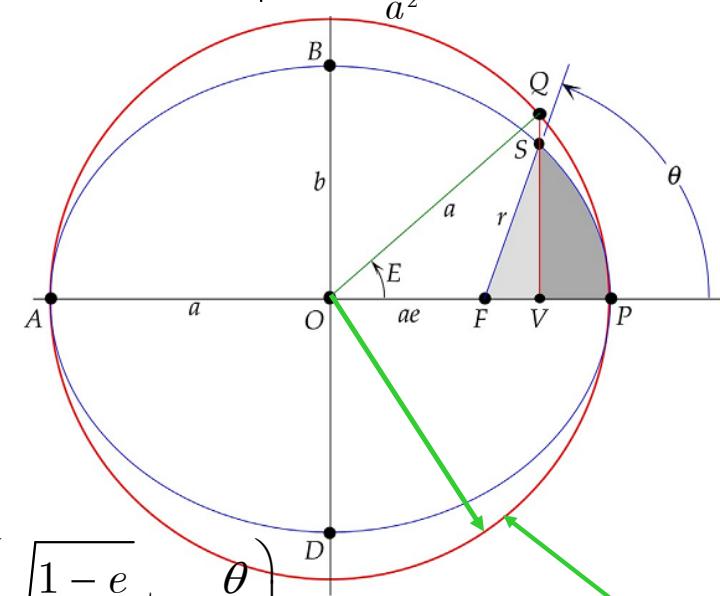

$$OV = a \cos E = ae + r \cos \theta$$

$$a \cos E = ae + \frac{a(1 - e^2) \cos \theta}{1 + e \cos \theta} \Rightarrow \cos E = \frac{e + \cos \theta}{1 + e \cos \theta} \Rightarrow E = 2 \tan^{-1} \left( \sqrt{\frac{1 - e}{1 + e}} \tan \frac{\theta}{2} \right)$$

$$\Rightarrow M_e = \left( 2 \tan^{-1} \sqrt{\frac{1 - e}{1 + e}} \tan \frac{\theta}{2} - \frac{e \sqrt{1 - e^2} \sin \theta}{1 + e \cos \theta} \right) = E - e \sin E = nt$$

$$\theta \rightarrow E \xrightarrow{n} t$$

$$\text{Note: } \tau = 2\pi \sqrt{\frac{a^3}{\mu}} \Rightarrow \frac{\mu^{\frac{1}{2}}}{a^{\frac{3}{2}}} = \frac{2\pi}{\tau} = n$$

## Example 5

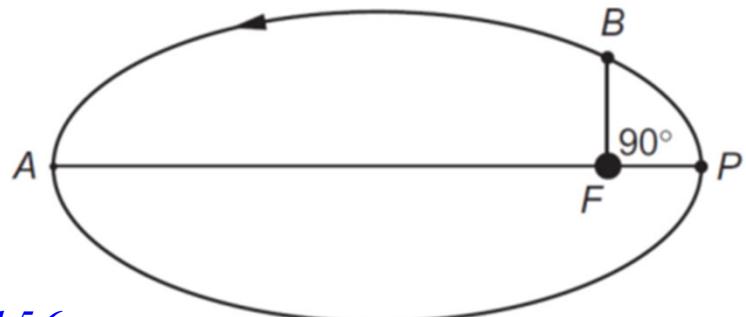

---

The eccentricity of an elliptic orbit is equal to 0.3, determine the time needed to reach point B as a fraction of the orbital period.

$$E - e \sin E = nt; \quad \tau = 2\pi \sqrt{\frac{a^3}{\mu}}; \quad n = \frac{2\pi}{\tau}$$

$$\cos E = \frac{e + \cos \theta}{1 + e \cos \theta} = e \Rightarrow E = 72.54 \text{ deg}$$

$$\frac{2\pi}{\tau} t = 72.54 \times \frac{\pi}{180} - 0.3 \sin(72.54) = 0.979 \Rightarrow t = 0.156\tau$$

## Example 6

---

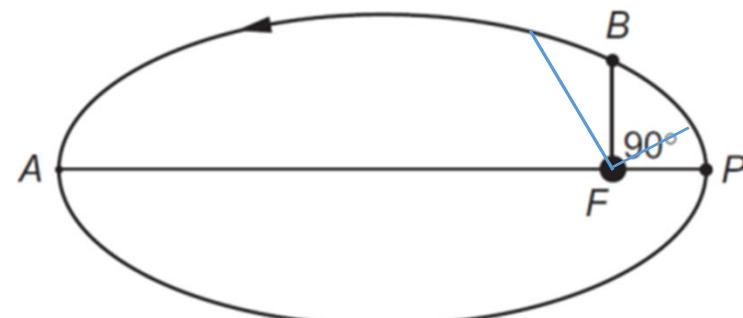

Compute the flight time between the true anomalies of 30 to 120 degrees , for an Earth orbiting satellite where  $e=0.6$  and  $P=4000 \text{ km}$ .

$$E - e \sin E = nt; \quad \tau = 2\pi \sqrt{\frac{a^3}{\mu}}; \quad n = \frac{2\pi}{\tau}; \quad P = a(1 - e^2); \quad \cos E = \frac{e + \cos \theta}{1 + e \cos \theta}$$

$$a = 6250 \text{ Km}, E_{30} = 15.26^\circ, E_{120} = 81.78^\circ, \tau = 4917.2 \text{ sec}$$

$$\Rightarrow t_{30} = 84.86 \text{ sec}, t_{120} = 652 \text{ sec}$$

$$\Rightarrow \Delta t = 576.14 \text{ sec}$$

## Example 7

A space probe is in an elliptical orbit around the Sun. Perihelion distance is .5 AU and the Apohelion is 2.5 AU. How many days during each orbit is the probe closer than 1 AU to the Sun?

$$\begin{cases} r_p = 0.5 \text{ AU}, r_a = 2.5 \text{ AU} \\ r_I = 1 \text{ AU}, \quad r_2 = 1 \text{ AU} \end{cases}$$

$$e = \frac{r_a - r_p}{r_a + r_p} = \frac{2}{3} \rightarrow a = \frac{r_p + r_a}{2} = \frac{3}{2}$$

$$p = a(1 - e^2) = 0.83333$$

$$r = \frac{a(1 - e^2)}{1 + e \cos \theta} = 1, \cos \theta = -\frac{1}{4}$$

$$\Rightarrow \theta_{1,2} = 104.47 \text{ and } 255.53$$

$$\cos E = \frac{e + \cos \theta}{1 + e \cos \theta} = 0.5$$

$$E = 60^\circ = 1.048 \text{ radians}, \sin E = 0.866$$

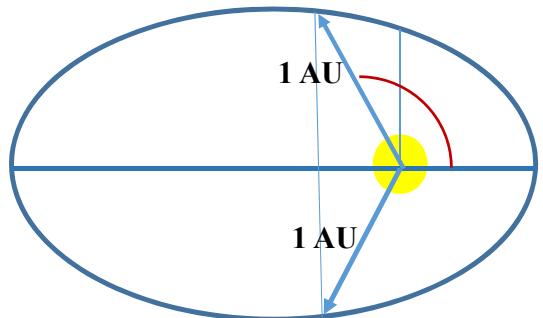

$$\tau = 2\pi \sqrt{\frac{a^3}{\mu}} = 4.78 \text{ TU}$$

$$n = \frac{2\pi}{\tau} = \sqrt{\frac{\mu}{a^3}}$$

$$E - e \sin E = nt$$

$$\left[ 1.048 - \frac{2}{3}(0.866) \right] = \sqrt{\frac{\mu}{a^3}} t \Rightarrow t = 0.862 \text{ TU}_\odot$$

$$TOF = 2t = 1.724 \text{ TU}_\odot \approx (1.724 / 2\pi) 365.24 = 100 \text{ Days}$$

# Elliptical Orbits ( $0 < e < 1$ )

2(d)- Elliptical Orbits: indirect problem via utility of Eccentric anomaly ( $E$ )

$$\cos E = \frac{e + \cos \theta}{1 + e \cos \theta} \Rightarrow E = 2 \tan^{-1} \left( \sqrt{\frac{1-e}{1+e}} \tan \frac{\theta}{2} \right); n = \frac{2\pi}{\tau} = \sqrt{\frac{\mu}{a^3}}$$

Direct problem :  $\theta \rightarrow E \xrightarrow{n} t_p : M_e = E - e \sin E = nt_p$ ,

Indirect problem :  $t_p \xrightarrow{n} M_e = E - e \sin E \rightarrow \theta$

$$f(E) = E - e \sin E - M_e \Rightarrow f'(E) = 1 - e \cos E$$

Utility of the iterative Newton's Root finding Method:

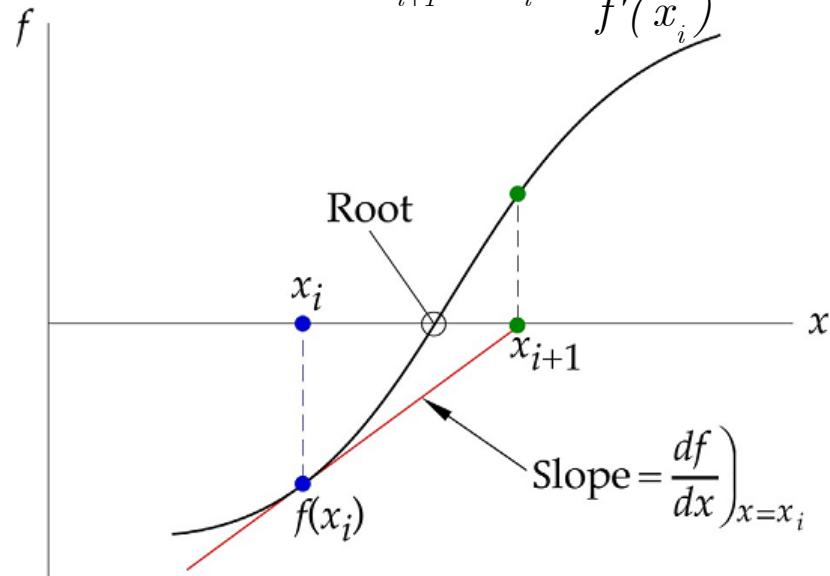

$$E_{i+1} = E_i - \frac{E_i - e \sin E_i - M_e}{1 - e \cos E_i}$$

$$E_0 = \begin{cases} M_e + e / 2, & M_e < \pi \\ M_e - e / 2, & M_e > \pi \end{cases}$$

Stopping Criterion :  $|E_{i+1} - E_i| < \varepsilon$  or  $|f(E_{i+1})| < \varepsilon$

$$f(x) = 0$$

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)}$$

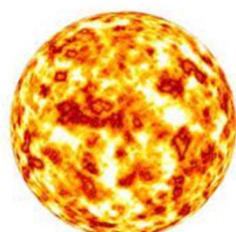

## Example 8

### EXAMPLE 3.3

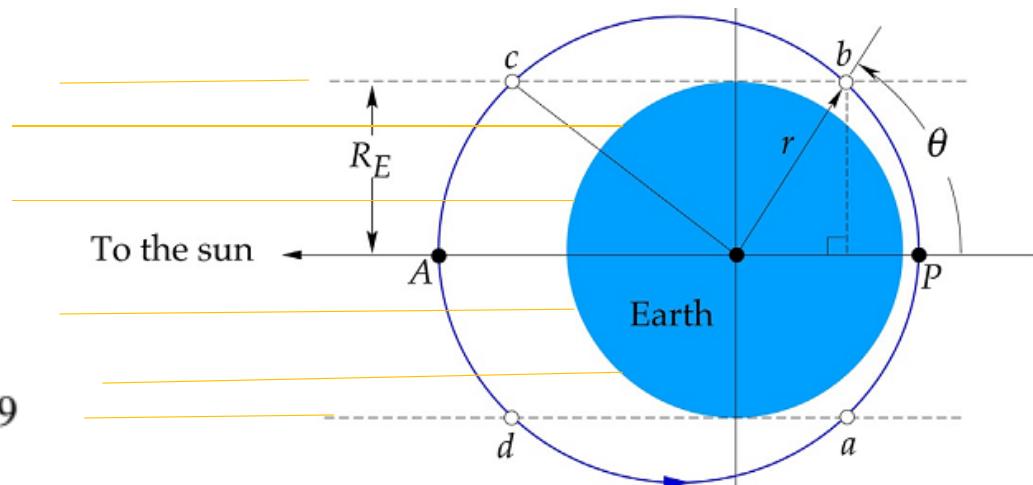

Let a satellite be in a 500 km by 5000 km orbit with its apse line parallel to the line from the earth to the sun, as shown in Fig. 3.9. Find the time that the satellite is in the earth's shadow if

- (a) the apogee is toward the sun
- (b) the perigee is toward the sun.

$$e = \frac{r_a - r_p}{r_a + r_p} = \frac{(6378 + 5000) - (6378 + 5000)}{(6378 + 5000) + (6378 + 5000)} = 0.24649$$

$$r_p = \frac{h^2}{\mu} \frac{1}{1 + e \cos(0)} \Rightarrow 6878 = \frac{h^2}{398,600} \frac{1}{1 + 0.24649} \Rightarrow h = 58,458 \text{ km}^2/\text{s}$$

## Example 8

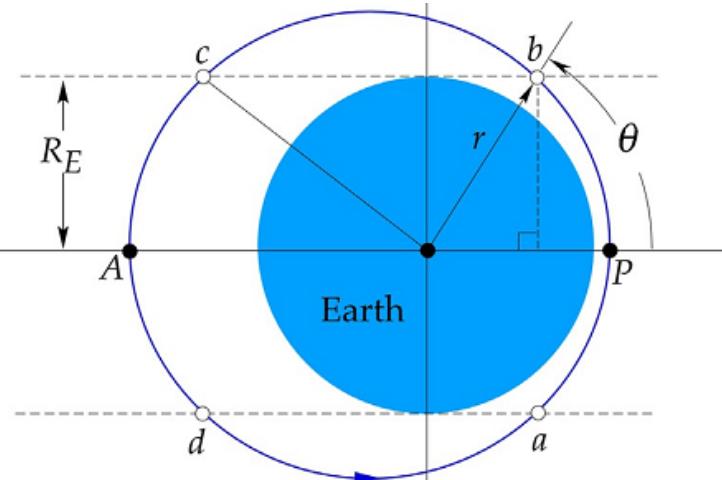

$$a = \frac{h^2}{\mu} \frac{1}{1-e^2} = \frac{58,458^2}{398,600} \frac{1}{1-0.24649^2} = 9128 \text{ km}$$

$$T = \frac{2\pi}{\sqrt{\mu}} a^{3/2} = \frac{2\pi}{\sqrt{398,600}} 9128^{3/2} = 86791.1 \text{ s} (2.4109 \text{ h})$$

$$\sin \theta = R_E/r, \quad r = \frac{a(1-e^2)}{1+e\cos\theta} \quad \rightarrow \quad e\cos\theta - (1-e^2) \frac{a}{R_E} \sin\theta + 1 = 0$$

$$0.24649 \cos\theta - 1.3442 \sin\theta = -1$$

To the sun

**Note:**

$$A \cos\theta + B \sin\theta = C$$

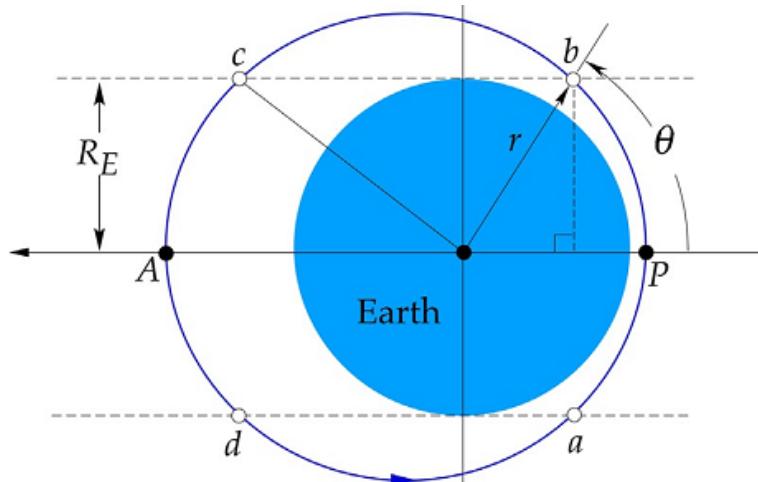

$$\theta = \tan^{-1} \frac{B}{A} \pm \cos^{-1} \left[ \frac{C}{A} \cos \left( \tan^{-1} \frac{B}{A} \right) \right]$$

## Example 8

$$\theta = \tan^{-1} \frac{-1.3442}{0.24649} \pm \cos^{-1} \left[ \frac{-1}{0.24649} \cos \left( \tan^{-1} \frac{-1.3442}{0.24649} \right) \right] = -79.607^\circ \pm 137.03^\circ$$

$$\theta_b = 57.423^\circ$$

$$\theta_c = -216.64^\circ (+143.36^\circ)$$

$$E_b = 2 \tan^{-1} \left( \sqrt{\frac{1-e}{1+e}} \tan \frac{\theta_b}{2} \right) = 2 \tan^{-1} \left( \sqrt{\frac{1-0.24649}{1+0.24649}} \tan \frac{57.423^\circ}{2} \right) = 0.80521 \text{ rad}$$

$$M_e = E - e \sin E = 0.80521 - 0.24649 \sin 0.80521 = 0.62749 \text{ rad}$$

$$t_b = \frac{M_e}{2\pi} T = \frac{0.62749}{2\pi} 8679.1 = 866.77 \text{ s}$$

$$t = 2t_h = 1734\text{ s} (28.98\text{ min})$$

# Parabolic Trajectories ( $e = 1$ )

3(a) -Direct Problem:

Parabolic Orbits time via Parabolic Mean Anomaly (PMA)

$$\frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1 + \cos \theta)^2} = \frac{1}{2} \tan \frac{\theta}{2} + \frac{1}{6} \tan^3 \frac{\theta}{2} = M_P$$

$$M_P = \frac{\mu^2 t}{h^3}$$

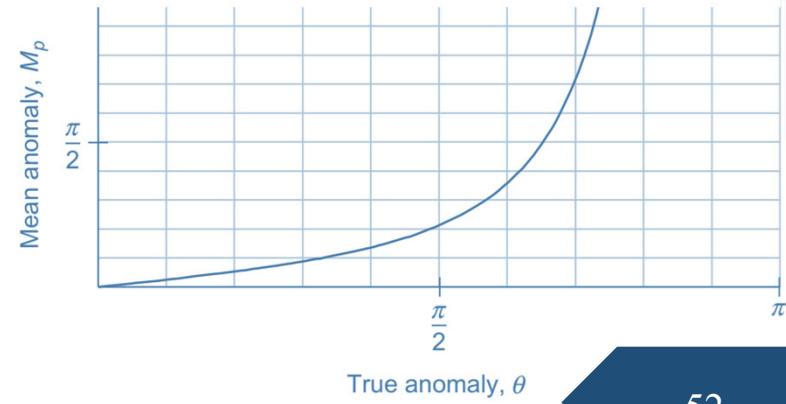

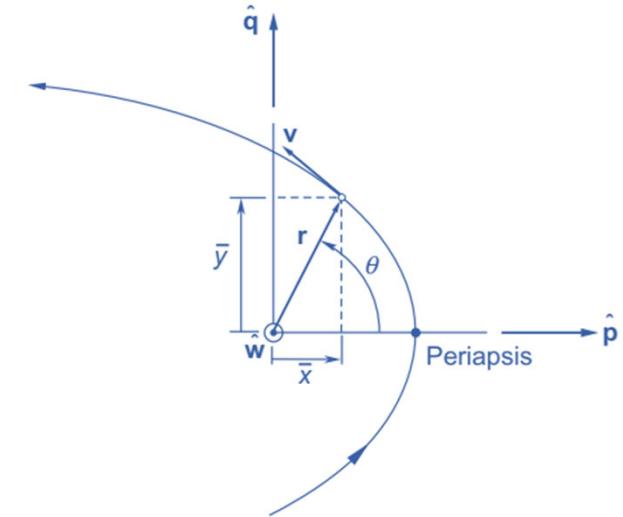

3(b) -Indirect Problem:

Parabolic Orbits position via Parabolic Mean Anomaly (PMA)

$$M_P = \frac{\mu^2 t}{h^3}$$

$$\text{Let : } b = 3M_P + \sqrt{(3M_P)^2 + 1}$$

$$\tan \frac{\theta}{2} = \left( b \right)^{\frac{1}{3}} - \left( b \right)^{-\frac{1}{3}}$$

## Example 9

An Earth bound space probe on a parabolic path has a perigee velocity of 10 Km/s. What will be its outbound altitude after **6 hours** passage from the perigee ?

$$\mu_{\text{earth}} = 398,600 \text{ km}^3 / \text{s}^2; v_{\text{esc}} = \sqrt{\frac{2\mu}{r}}$$

$$v_p = 10 \Rightarrow r_p = \frac{2\mu}{v_p^2} = 7972 \text{ km}$$

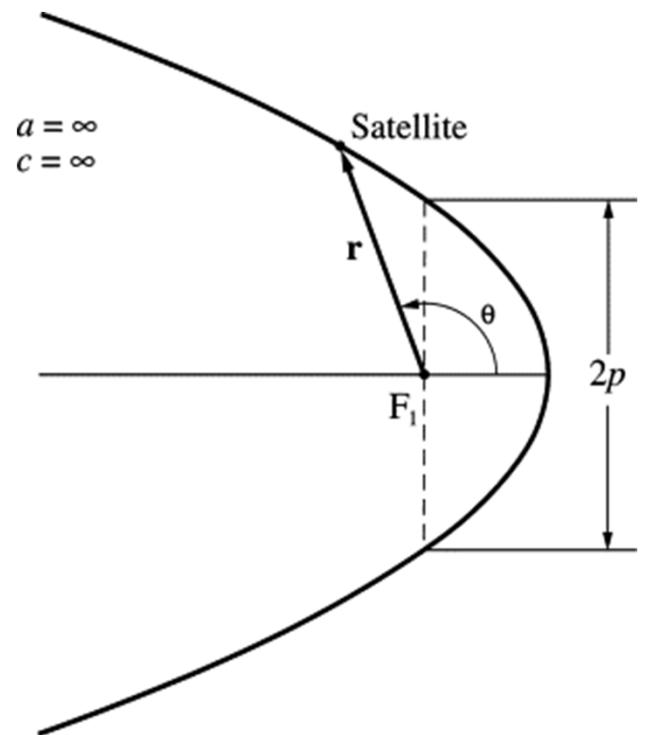

$$h = r_p v_p = 7972 \text{ km}^2 / \text{s}$$

$$M_P = \frac{\mu^2 t}{h^3} = \frac{\mu^2}{h^3} (6 \times 3600) = 6.7737 \text{ Rad}$$

$$b = 3M_P + \sqrt{(3M_P)^2 + I} = 3 \times 6.7737 + \sqrt{(3 \times 6.7737)^2 + I} = 40.66$$

$$\tan \frac{\theta}{2} = (b)^{\frac{1}{3}} - (b)^{-\frac{1}{3}} = 3.148 \Rightarrow \theta = 144.75^\circ$$

$$r = \frac{h^2 / \mu}{1 + \cos \theta} = 86899 \text{ km} \Rightarrow H = r - R_E = 80,521 \text{ km}$$

# Hyperbolic Trajectories ( $e > 1$ )

4(a) - Hyperbolic Orbits time via Hyperbolic Mean Anomaly (HMA)

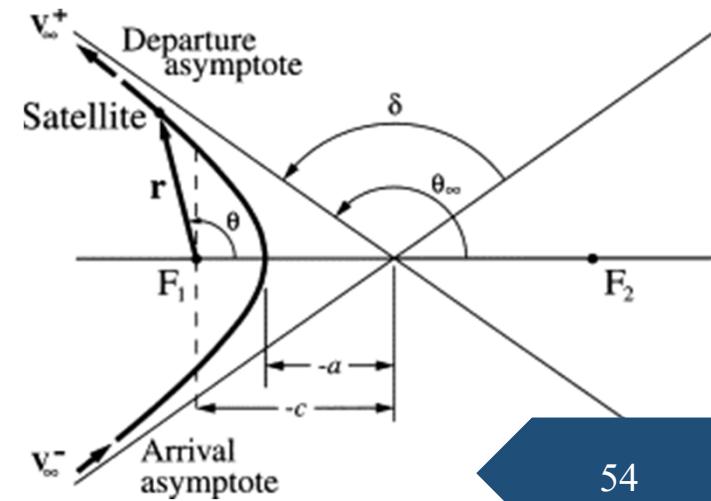

$$\frac{\mu^2}{h^3} t = \int_0^\theta \frac{d\theta}{(1 + e \cos \theta)^2} = \frac{1}{e^2 - 1} \left[ \frac{e \sin \theta}{1 + e \cos \theta} - \frac{1}{\sqrt{e^2 - 1}} \ln \left( \frac{\sqrt{e+1} + \sqrt{e-1} \tan(\theta/2)}{\sqrt{e+1} - \sqrt{e-1} \tan(\theta/2)} \right) \right]$$

$$\frac{\mu^2}{h^3} t = \frac{1}{e^2 - 1} \frac{e \sin \theta}{1 + e \cos \theta} - \frac{1}{(e^2 - 1)^{\frac{3}{2}}} \ln \left( \frac{\sqrt{e+1} + \sqrt{e-1} \tan(\theta/2)}{\sqrt{e+1} - \sqrt{e-1} \tan(\theta/2)} \right) \xrightarrow{\times (e^2 - 1)^{\frac{3}{2}}}$$

$$\frac{\mu^2}{h^3} (e^2 - 1)^{\frac{3}{2}} t = \frac{e \sqrt{e^2 - 1} \sin \theta}{1 + e \cos \theta} - \ln \left( \frac{\sqrt{e+1} + \sqrt{e-1} \tan(\theta/2)}{\sqrt{e+1} - \sqrt{e-1} \tan(\theta/2)} \right)$$

$M_h$  = Hyperbolic Mean Anomaly

$$\frac{\mu^2}{h^3} (e^2 - 1)^{\frac{3}{2}} t_p = M_h$$

# Hyperbolic Trajectories ( $e > 1$ )

4(b) - Hyperbolic Orbits time via utility of  
Hyperbolic Eccentric Anomaly (HEA),  $F$

$$M_h = e \sinh F - F = \frac{\mu^2}{h^3} (e^2 - 1)^{\frac{3}{2}} t$$

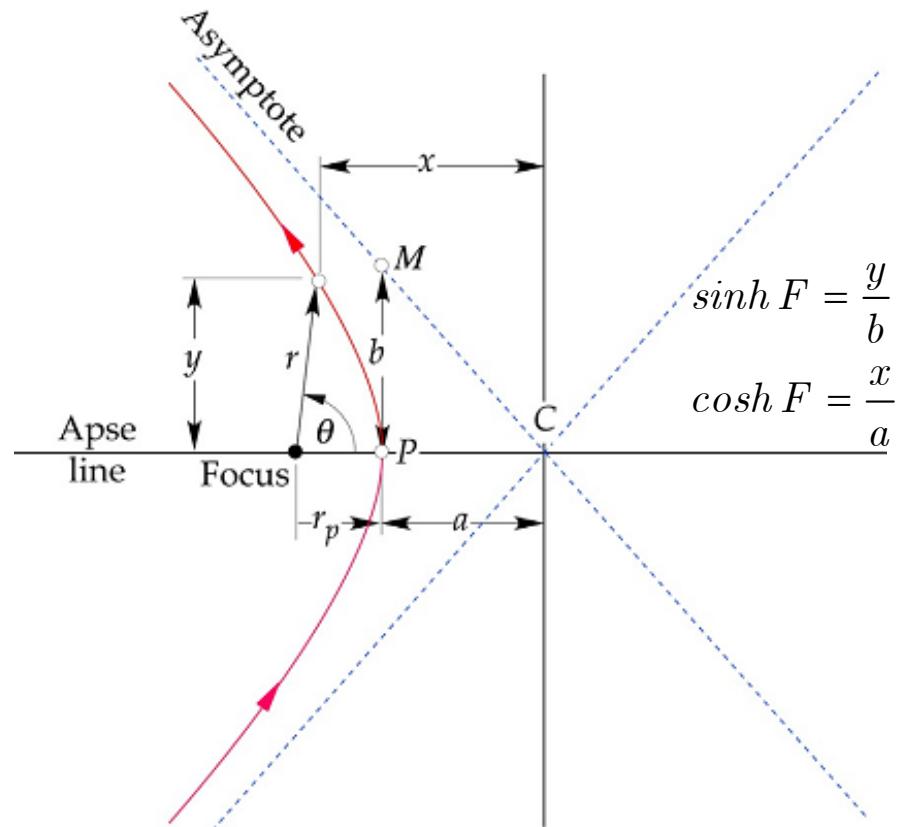

$$\tanh \frac{F}{2} = \sqrt{\frac{e-1}{e+1}} \tanh \frac{\theta}{2}$$

4(c) - Indirect Problem

Hyperbolic Orbits position from time via  
Newton's Root Finding Method

$$f(F) = e \sinh F - F - M_h = 0 \Rightarrow F \Rightarrow \theta$$

$$\tanh \frac{F}{2} = \sqrt{\frac{e-1}{e+1}} \tanh \frac{\theta}{2}$$

## Example 10

A meteorite has been spotted to approach the Earth at an **altitude** of 37000 km with a speed of 8 km/s. if at the time of initial observation its flight path is -65 degrees,

- 1- investigate the possibility of its encounter with the Earth or find the closest approach distance.
- 2- Time to closest approach, if there is no impact.

### 1-Impact Check

$$\varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = 22.81 > 0 \Rightarrow \text{Hyperbolic Trajectory}$$

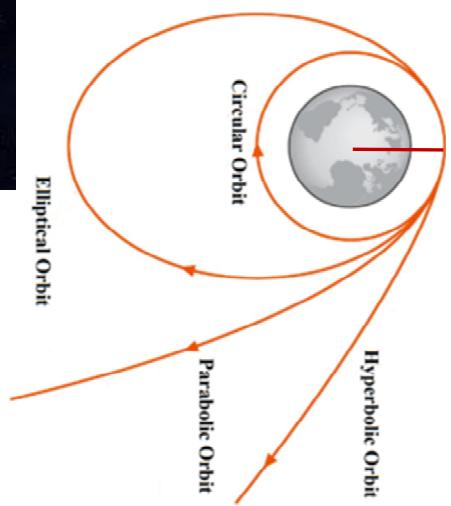

$$h = rvcos\gamma = 1.467e+5 \text{ km}^2/\text{s}$$

$$\varepsilon = -\frac{1}{2} \frac{\mu^2}{h^2} (1-e^2) \Rightarrow e = 2.678$$

$$P = \frac{h^2}{\mu} = 53961$$

$$r_p = P/(1+e) = 14671.2 > R_E \Rightarrow \text{No Encounter!}$$

$$\text{Closest Approach} = r_p - R_E = 5605 \text{ km}$$

$$r = \frac{53961}{1 + 2.678 \cos \theta}$$

## Example 10

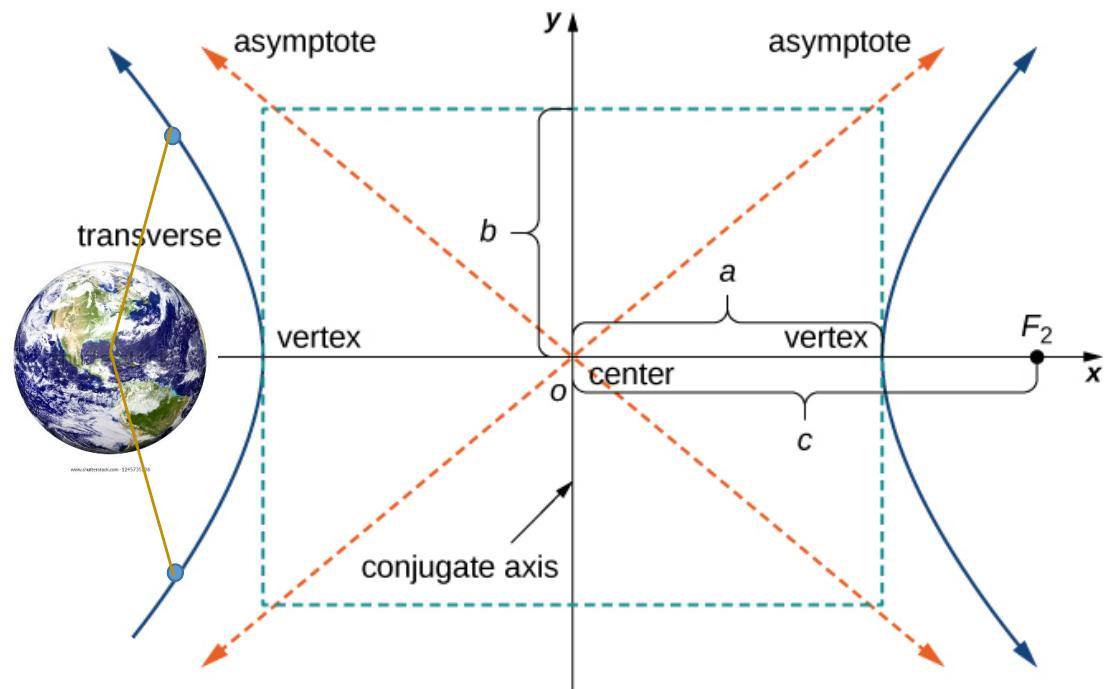

2-Time to closest approach

$$r = \frac{53961}{1 + 2.678 \cos \theta} = 37000 + 6378.145 \Rightarrow \theta = 84.77 \text{ or } -84.77$$

$$\tanh \frac{F}{2} = \sqrt{\frac{e-1}{e+1}} \tanh \frac{\theta}{2} \Rightarrow \tanh \frac{F}{2} \sqrt{\frac{e+1}{e-1}} = \tanh \frac{\theta}{2} \Rightarrow F = 1.44 \text{ Rad}$$

$$M_h = e \sinh F - F = 3.886$$

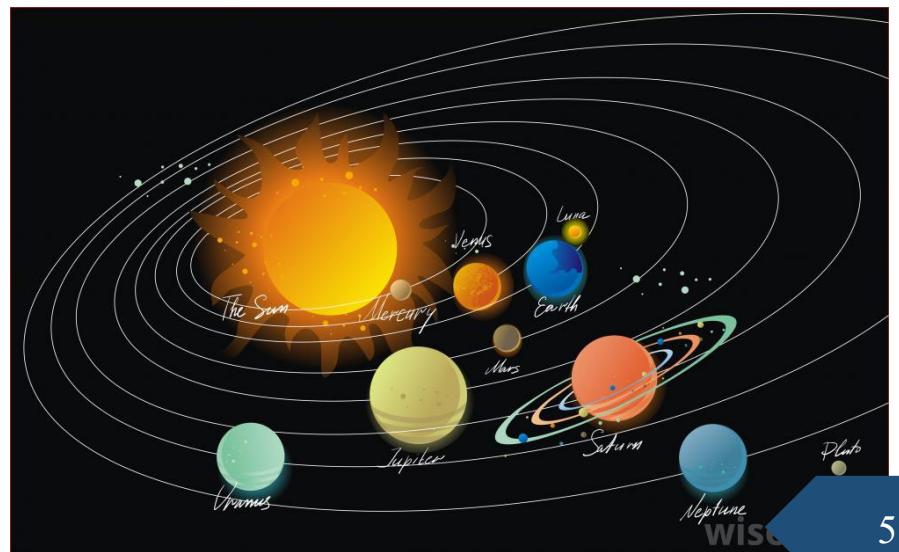

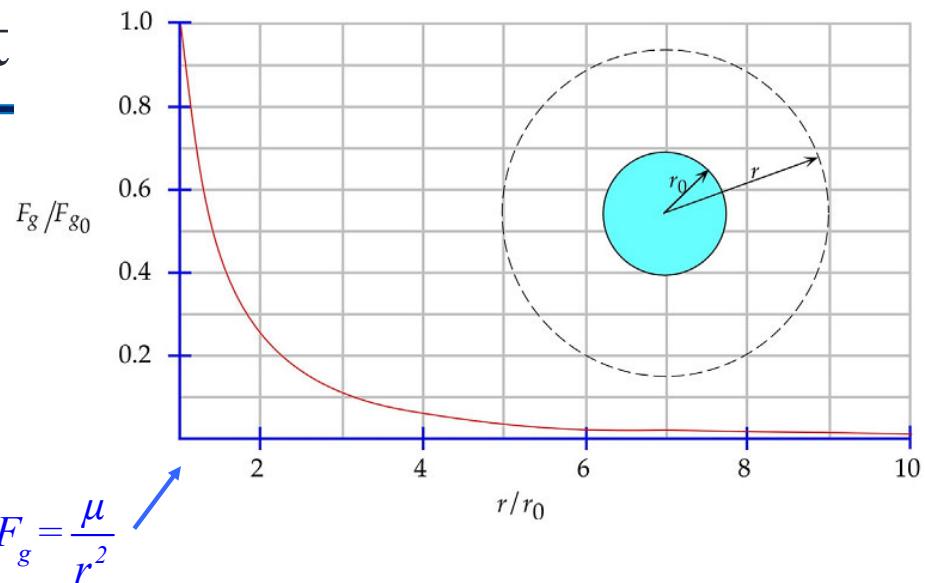

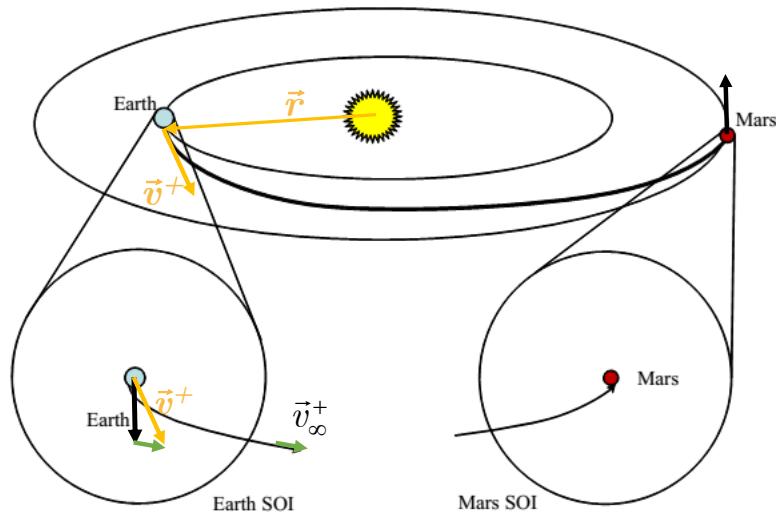

$$M_h = \frac{\mu^2}{h^3} (e^2 - 1)^{\frac{3}{2}} t \Rightarrow t = 5032.8 = 1 \text{ hr} + 24 \text{ min}$$

# Sphere of Influence (SOI) Concept

The Sun is the dominant mass within the solar system. It is more than 300,000 times heavier than the Earth.

However, to determine the domain of attraction of each planet within the solar system, an sphere of influence (SOI) is defined as a region around each celestial body where the primary gravitational influence on any orbiting object is that of the celestial body.

# Method of Patched Conics for Interplanetary Transfer

---

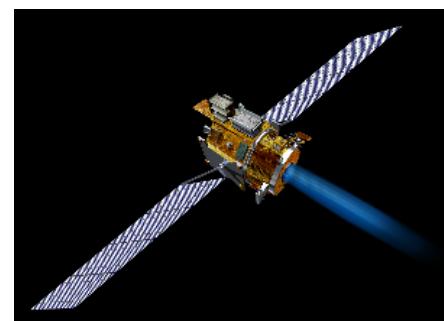

Celestial Body	SOI radius ( $10^6$ km)	SOI radius /(Celestial body radii)
<u>Mercury</u>	0.112	46
<u>Venus</u>	0.616	102
<u>Earth</u>	0.925	145
<u>Moon</u>	0.0661	38
<u>Mars</u>	0.578	170
<u>Jupiter</u>	48.2	687
<u>Saturn</u>	54.5	1025
<u>Uranus</u>	51.9	2040
<u>Neptune</u>	86.8	3525

# Orbital transfer (OT) or Maneuvers

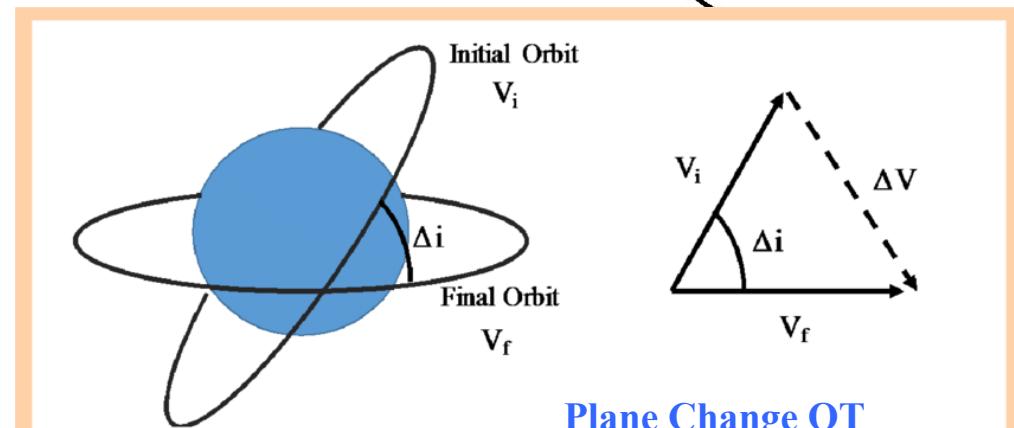

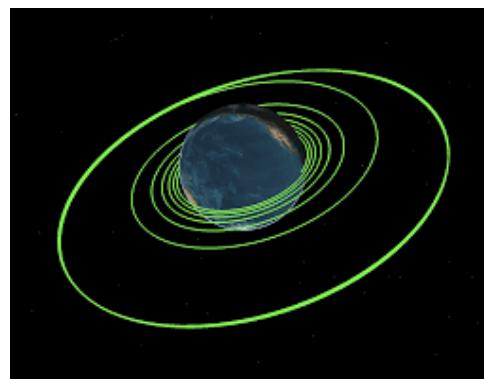

**Orbital maneuvers** are performed to transfer a spacecraft from one orbit to another using a velocity change ( $\Delta V$ ). **Impulsive Orbital transfer** can be justified since the thrust duration is short relative to the orbital period. A simple classification of OT methods are as follows:

## Impulsive Maneuvers

- Hohmann Transfer
- Non-Hohmann Transfers
- Phasing Maneuvers
- Plane Change Maneuvers

## Non-impulsive Orbital Maneuvers

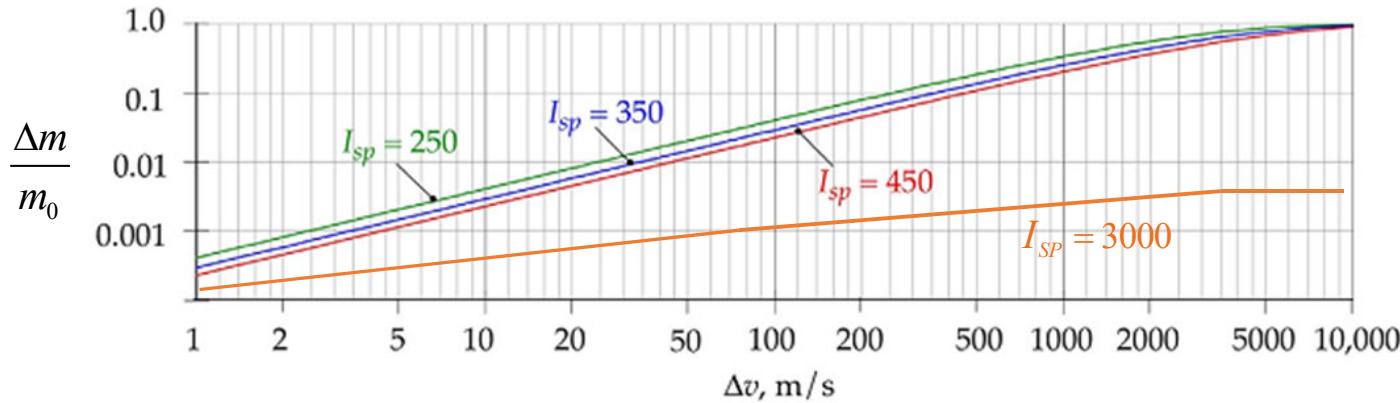

# Impulsive Maneuvers

Impulsive maneuvers are those in which brief firings of onboard rocket motors change the magnitude and direction of the velocity vector instantaneously. During an impulsive maneuver, the position of the spacecraft is considered to be fixed; only the velocity changes. The magnitude  $\Delta V$  of the velocity increment is related to  $\Delta m$  that is equal to Initial mass minus the final mass (i.e. the mass of propellant consumed), via the ideal rocket equation (Tsiolkovsky rocket equation). Where Isp is the specific impulse of the propellants as defined below.

$$\frac{\Delta m}{m_0} = 1 - e^{-\frac{\Delta V}{I_{sp}g_0}} \Rightarrow \Delta V = I_{sp}g_0 \ln\left(\frac{m_0}{m_f}\right) - \cancel{\Delta V_D} - \cancel{\Delta V_g}$$

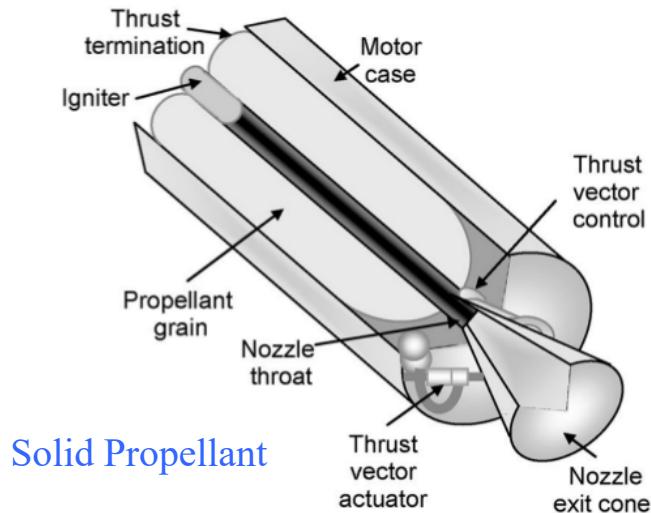

$$I_{sp} (\text{Specific impulse}) = \frac{\text{Thrust}}{\text{Sea level weight rate of fuel consumption}} \text{ in Sec.} = \frac{T}{\dot{m}_f g_0}$$

$g_0$ : the sea-level standard acceleration of gravity;  $\Delta m = m_0 - m_f$

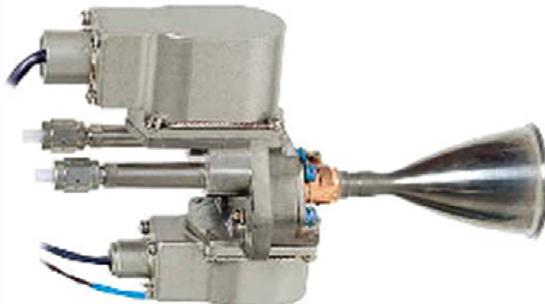

Propellant	$I_{sp}$ (s)
Cold gas	50
Monopropellant hydrazine	230
Solid propellant	290
Nitric acid/monomethylhydrazine	310
Liquid oxygen/liquid hydrogen	455
Ion propulsion	>3000

# Impulsive Maneuvers: Typical Thrusters

Solid Propellant

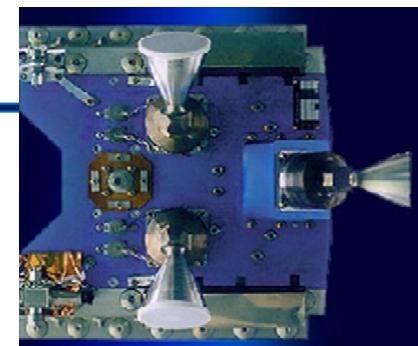

10N Bipropellant Thrusters

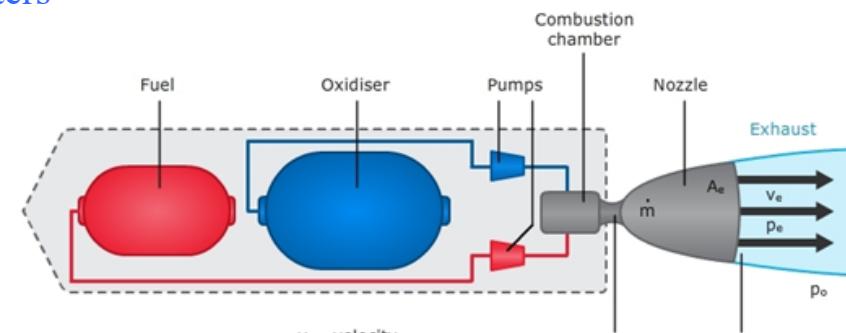

Cold Gas Thrusters

Electric or Ion Thrusters

1-400N Hydrazine Thrusters

$$\text{Thrust} = F = \dot{m} v_e + (p_e - p_0) A_e$$

Liquid Propellant

# Impulsive Maneuvers: Typical Thrusters

Propulsion methods					
Method	Effective exhaust velocity (km/s)	Thrust (N)	Firing duration	Maximum delta-v (km/s)	Technology readiness level
Solid-fuel rocket	<2.5	< $10^7$	Minutes	7	9: Flight proven
Monopropellant rocket	1 – 3[35]	0.1 – 400[35]	Milliseconds – minutes	3	9: Flight proven
Liquid-fuel rocket	<4.4	< $10^7$	Minutes	9	9: Flight proven
Hybrid rocket	<4		Minutes	>3	9: Flight proven

Technology Readiness Levels (TRL) are a method used to measure and assess the maturity of a particular technology.

TRL	Current NASA usage
1	Basic principles observed and reported
2	Technology concept and/or application formulated
3	Analytical and experimental critical function and/or characteristic proof-of concept
4	Component and/or breadboard validation in laboratory environment

5	Component and/or breadboard validation in relevant environment
6	System/subsystem model or prototype demonstration in a relevant environment (ground or space)
7	System prototype demonstration in a space environment
8	Actual system completed and "flight qualified" through test and demonstration (ground or space)
9	Actual system "flight proven" through successful mission operations

# Hohmann Transfer (HT)

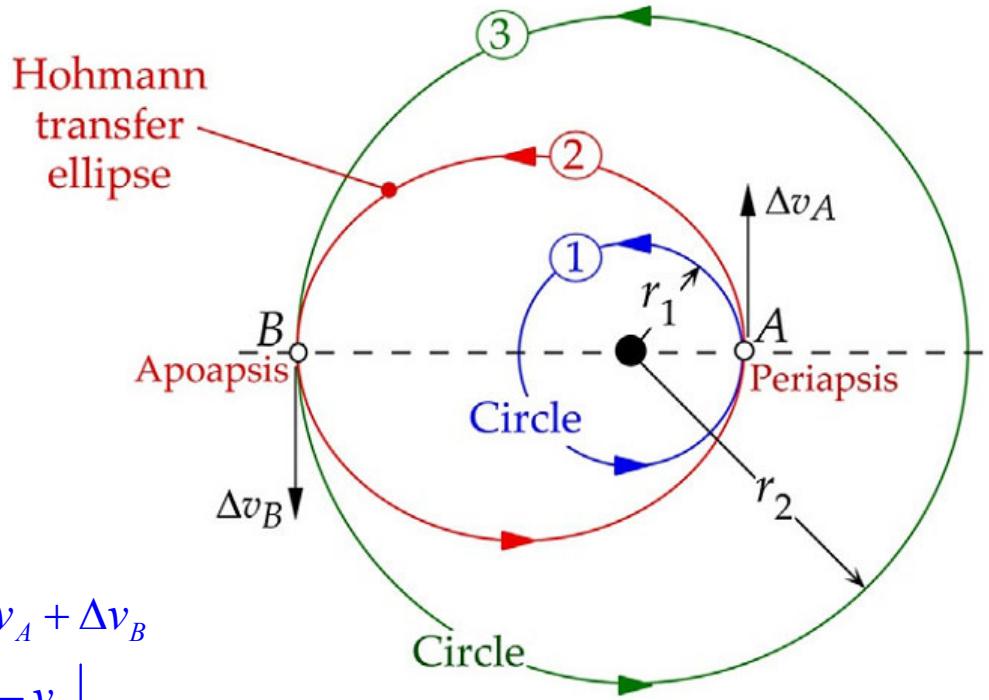

**Hohmann** transfer is the most energy-efficient two-impulse maneuver for transferring between two coplanar circular orbits sharing a common focus. The Hohmann transfer elliptic properties can be computed as follows:

$$r_a = \frac{P}{1-e}; r_p = \frac{P}{1+e} \Rightarrow e = \frac{r_a - r_p}{r_a + r_p}$$

$$r_p = \frac{h^2}{\mu} \frac{1}{1+e} = \frac{h^2}{\mu} \frac{1}{1 + \frac{r_a - r_p}{r_a + r_p}} = \frac{h^2}{\mu} \frac{r_a + r_p}{2r_a}$$

$$\Rightarrow h = \sqrt{2\mu} \sqrt{\frac{r_a r_p}{r_a + r_p}} \Rightarrow v_a; v_p$$

$$\left. \begin{aligned} \Delta v_{total} &= \Delta v_A + \Delta v_B \\ \Delta v_A &= |v_{C_1} - v_P| \\ \Delta v_B &= |v_a - v_{C_3}| \end{aligned} \right\}$$

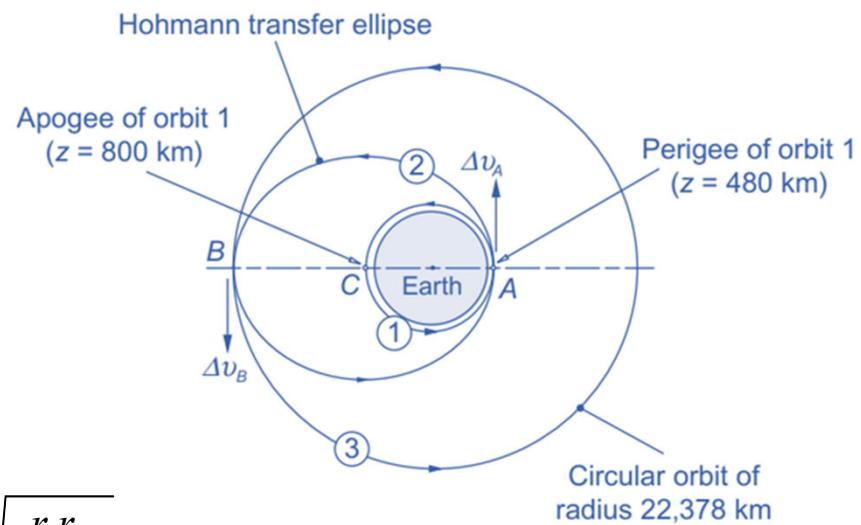

Hohmann transfer can in general be used for transfer between any two coplanar closed orbits sharing a common focus.

# Hohmann Transfer (HT) Example 11

Consider a 2000 kg spacecraft in a **480x800 km (altitude)**

Earth orbit, Find:

- 1- The  $\Delta v$  needed at Perigee point A of orbit 1, to place the spacecraft in a **480x16,000 km** HT transfer ellipse.
- 2- The  $\Delta v$  (Apogee kick) required at B of the HT transfer orbit to establish a circular orbit of 16,000 km altitude (orbit 3).
- 3) The total required propellant mass needed for this transfer, if the specific impulse is 300 s.

$$e_T = \frac{r_a - r_p}{r_a + r_p}; \quad h_T = \sqrt{2\mu} \sqrt{\frac{r_a r_p}{r_a + r_p}} \Rightarrow v_a; v_p$$

$$\Delta v_A = |v_1 - v_p|; \quad \Delta v_B = |v_a - v_{C_3}|$$

$$\Delta v_{total} = \Delta v_A + \Delta v_B$$

$$\frac{\Delta m}{m_0} = 1 - e^{-\frac{\Delta V}{I_{sp}g_0}}$$

$$\Delta m = m_0 - m_f$$

# Hohmann Transfer (HT) Example 11

Orbit 1:

$$r_p = 6378 + 480 = 6858 \text{ km} \quad r_a = 6378 + 800 = 7178 \text{ km}$$

$$\Rightarrow h_1 = \sqrt{2 \times 398,600} \sqrt{\frac{7178 \times 6858}{7178 + 6858}} = 52,876.5 \text{ km/s}^2$$

Orbit 2:

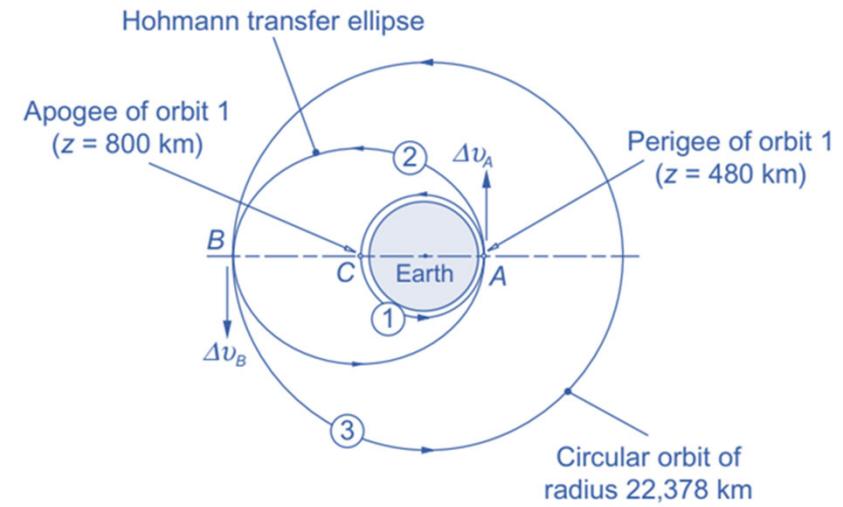

$$r_p = 6378 + 480 = 6858 \text{ km} \quad r_a = 6378 + 16,000 = 22,378 \text{ km}$$

$$\Rightarrow h_2 = \sqrt{2 \times 398,600} \sqrt{\frac{22,378 \times 6858}{22,378 + 6858}} = 64,689.5 \text{ km/s}^2$$

$$v_A)_1 = v_1 = \frac{h_1}{r_A} = \frac{52,876}{6858} = 7.71019 \text{ km/s}$$

$$v_A)_2 = v_P = \frac{h_2}{r_A} = \frac{64,689.5}{6858} = 9.43271 \text{ km/s}$$

$$\Delta v_A = v_P - v_1 = 1.7225 \text{ km/s}$$

$$h = \sqrt{2\mu} \sqrt{\frac{r_a r_p}{r_a + r_p}} \Rightarrow v_a; v_P$$

# Hohmann Transfer (HT) Example 11

Orbit 3:

$$r_a = r_p = P = 22,378 \text{ km}$$

$$\Rightarrow h_3 = \sqrt{398,600 \times 22,378} = 94,445.1 \text{ km/s}^2$$

$$v_B)_2 = v_a = \frac{h_2}{r_B} = \frac{64,689.5}{22,378} = 2.89076 \text{ km/s}$$

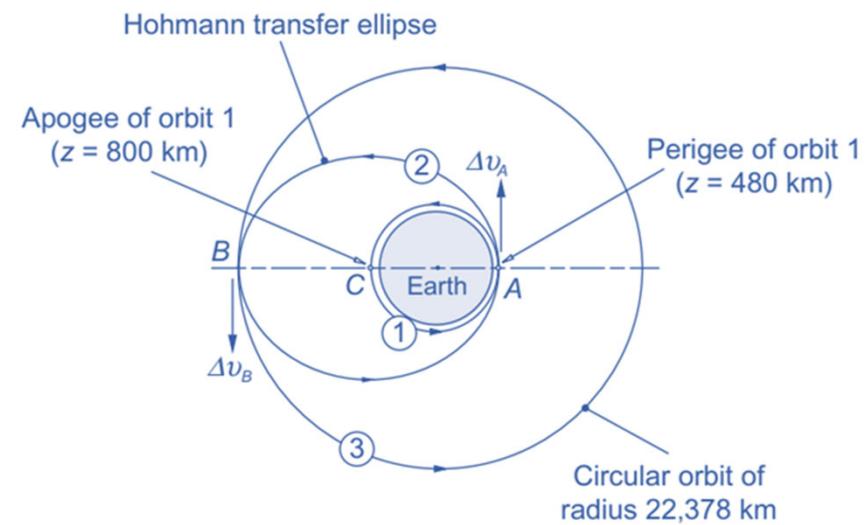

$$v_B)_3 = v_{C_3} = \frac{h_3}{r_B} = \frac{94,445.1}{22,378} = 4.22044 \text{ km/s}$$

$$\Delta v_B = v_B)_3 - v_B)_2 = 1.3297 \text{ km/s}$$

$$\Delta v_{total} = |\Delta v_A| + |\Delta v_B| = 1.7225 + 1.3297 = 3.0522 \text{ km/s}$$

$$\frac{\Delta m}{m_0} = 1 - e^{-\frac{3052.2}{300 \times 9.807}} = 0.64563$$

$$\Delta m = 0.64563 \times 2000 = 1291.3 \text{ kg}$$

$$\Delta v_B = |v_a - v_{C_3}|$$

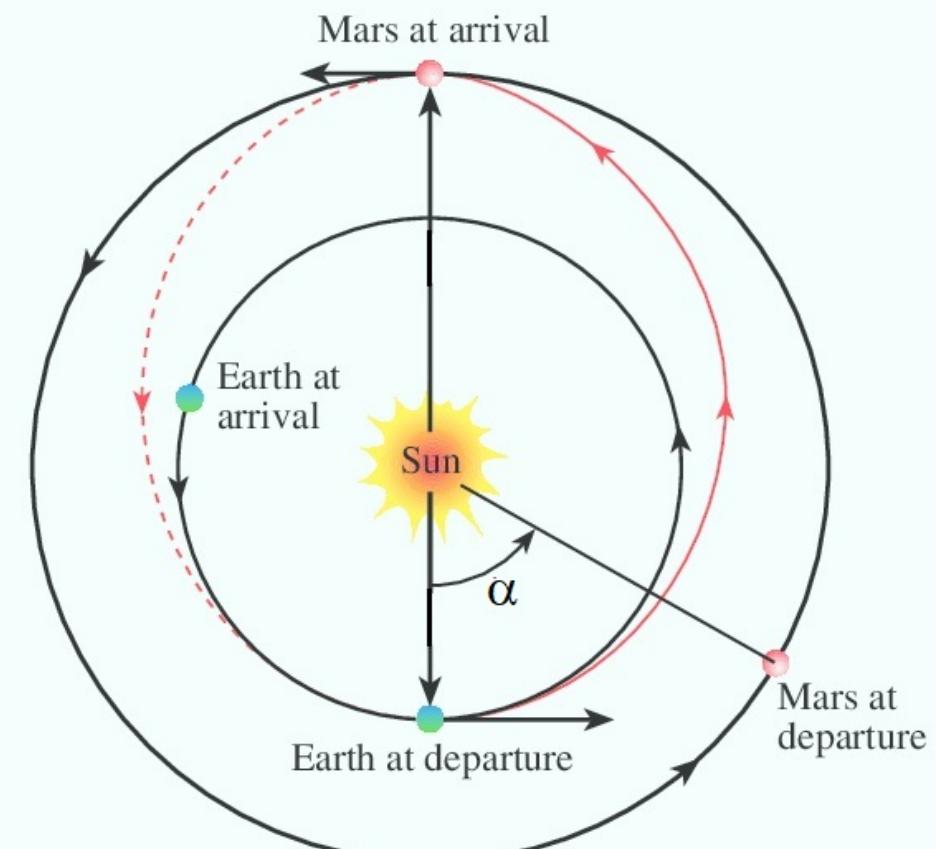

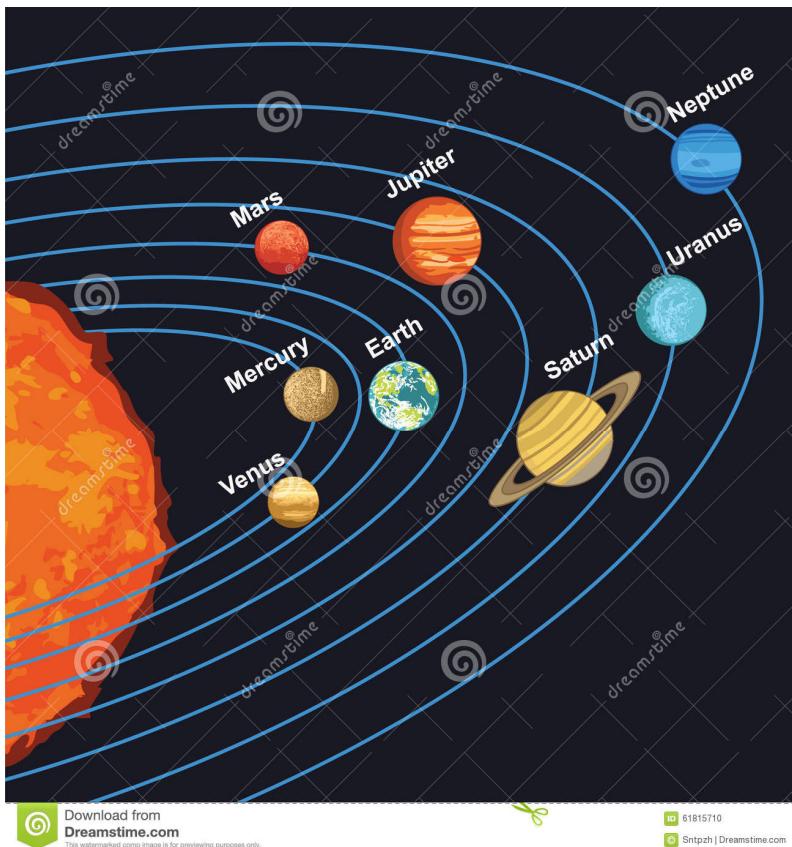

$$\Delta v_{total} = \Delta v_A + \Delta v_B$$

$$\frac{\Delta m}{m_0} = 1 - e^{-\frac{\Delta V}{I_{sp}g_0}}$$

$$\Delta m = m_0 - m_f$$

# Hohmann Transfer for interplanetary missions

**Hohmann** transfer can also be used by proper planning (launch window) to send a spacecraft from Low Earth (LEO) orbit to Mars or other planets .

# Bi-elliptic Hohmann Transfer (BE)

The HT between two circular orbits is efficient as long as the ratio of the bigger to smaller radius is smaller than 11.94 . In contrast Bi-elliptic Hohmann Transfer (BE), as a three impulse transfer is proposed for cases that contradict the above assumption. The idea behind BE is to place point B sufficiently far from the focus such that the required  $\Delta v_B$  to put the spacecraft on the target orbit (4) will be very small. It can be shown:

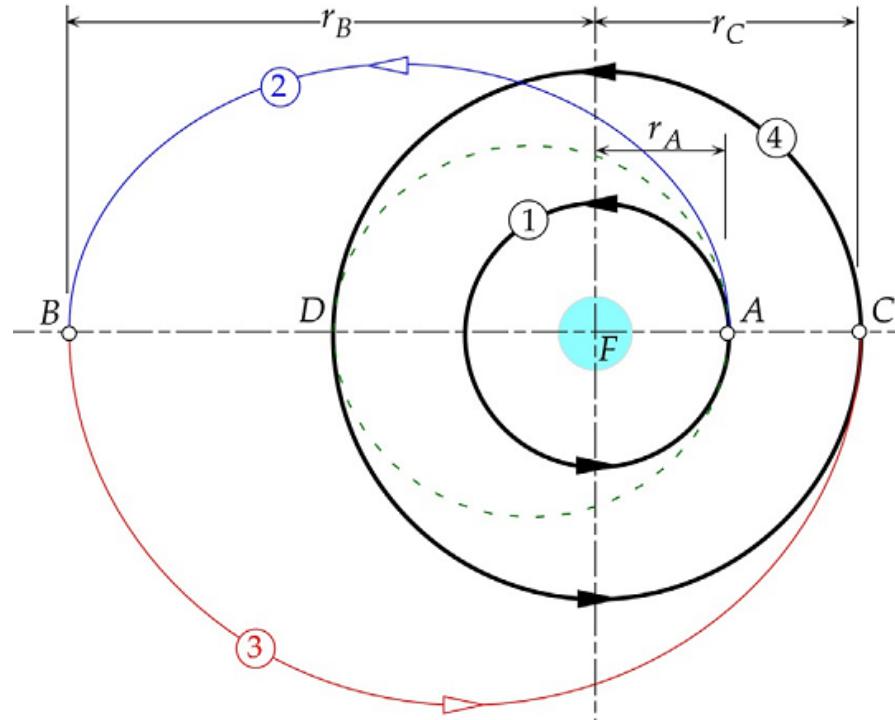

$$v_0 = \sqrt{\frac{\mu}{r_A}} ; \text{ speed in circular inner orbit 1}$$

$$\Delta \bar{v}_H = \frac{1}{\sqrt{\alpha}} - \frac{\sqrt{2}(1-\alpha)}{\sqrt{\alpha(1+\alpha)}} - 1$$

$$\Delta \bar{v}_{BE} = \sqrt{\frac{2(\alpha + \beta)}{\alpha\beta}} - \frac{1+\sqrt{\alpha}}{\sqrt{\alpha}} - \sqrt{\frac{2}{\beta(1+\beta)}}(1-\beta)$$

where :

$$\alpha = \frac{r_C}{r_A} \quad \beta = \frac{r_B}{r_A}$$

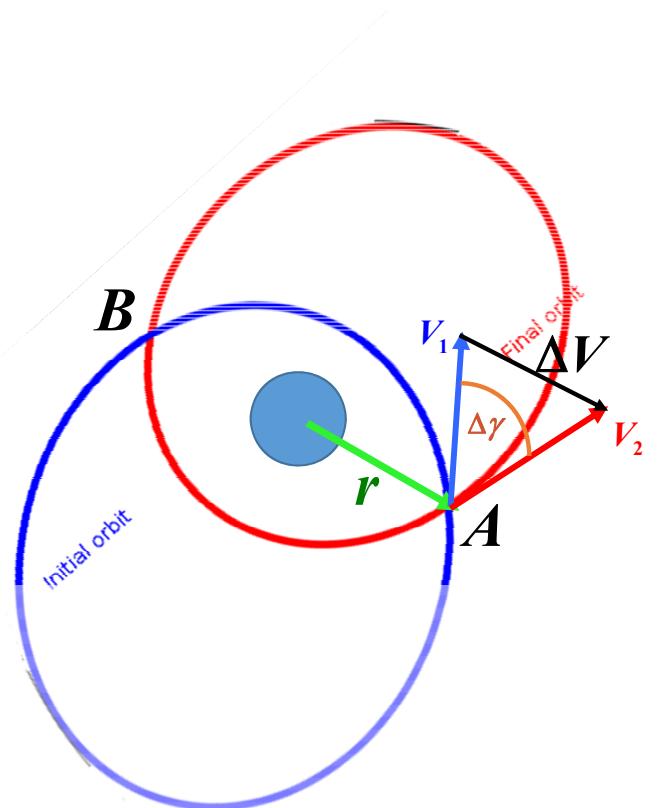

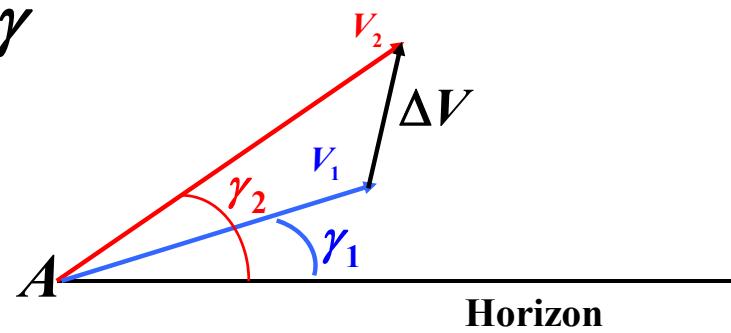

- 1: Initial Orbit
- 4: Target orbit
- 2: Auxiliary orbit
- 3: Auxiliary orbit

# Non-Hohmann Transfers

Single Impulsive transfer between two intersecting coplanar orbits is possible by computing the required  $\Delta V$  to switch from the initial orbit to final orbit at one of the intersection points. Computation of  $\Delta V$  is possible if the two orbit polar equations or properties are provided .

$$\Delta V^2 = V_1^2 + V_2^2 - 2V_1V_2 \cos \Delta\gamma$$

where :  $\Delta\gamma = \gamma_2 - \gamma_1$

## Example 11

Consider two coplanar Earth orbits with the given properties. It is desired to transfer from orbit 1 at the true anomaly of 150 deg. to orbit 2 , find the required  $\Delta V$  for this transfer.

*Orbit 1* :  $P_1 = 7200 \text{ Km}$ ;  $e_1 = 0.5$

*Orbit 2* :  $a_2 = 1.5a_1$ ;  $e_2 = 0.5$

$$P_1 = a_1(1 - e_1^2) \Rightarrow a_1 = 9600 \text{ Km} \Rightarrow a_2 = 14400 \text{ Km}$$

$$P_2 = a_2(1 - e_2^2) = 10800, \text{ at the intersection point } r_1 = r_2 = \frac{7200}{1 + 0.5 \cos 150} = 12698.7 \text{ Km}$$

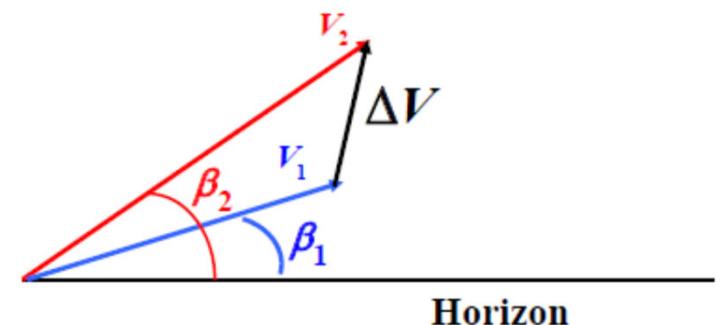

$$r_2 = 12698.7 = \frac{10800}{1 + 0.5 \cos \theta_2} \Rightarrow \theta_2 = 107.4 \text{ deg}$$

$$h_1 = r_1 v_1 \cos \beta_1 = (P_1 \mu)^{1/2} \Rightarrow \beta_1 = 23.76^\circ$$

$$h_2 = r_2 v_2 \cos \beta_2 = (P_2 \mu)^{1/2} \Rightarrow \beta_2 = 29.35^\circ$$

$$\varepsilon = \frac{v^2}{2} - \frac{\mu}{r} = -\frac{\mu}{2a} \Rightarrow v_1 = 4.61 \text{ km/s} \text{ and } v_2 = 5.92 \text{ km/s}$$

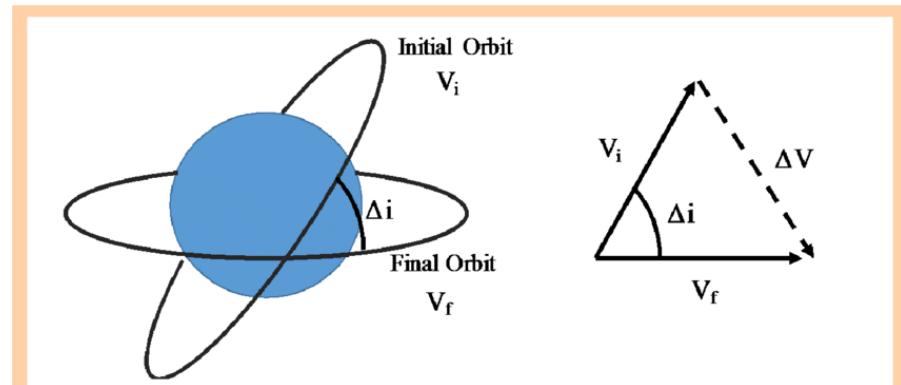

$$\Delta V^2 = V_1^2 + V_2^2 - 2V_1 V_2 \cos(\beta_2 - \beta_1) \Rightarrow \Delta V = 1.41 \text{ km/s}$$

# Plane Change Maneuvers (PCM) between intersecting orbits

Single Impulsive transfer between two intersecting

Non-coplanar circular orbits is possible by computing the required  $\Delta V$  to switch from the initial orbit to final orbit at one of the intersection points. If the initial and final orbits are not intersecting two impulsive  $\Delta V$  will be needed.

The thruster firing direction is important.

$$\Delta V^2 = V_i^2 + V_f^2 - 2V_i V_f \cos \Delta i$$

# Phasing Maneuvers for Rendezvous

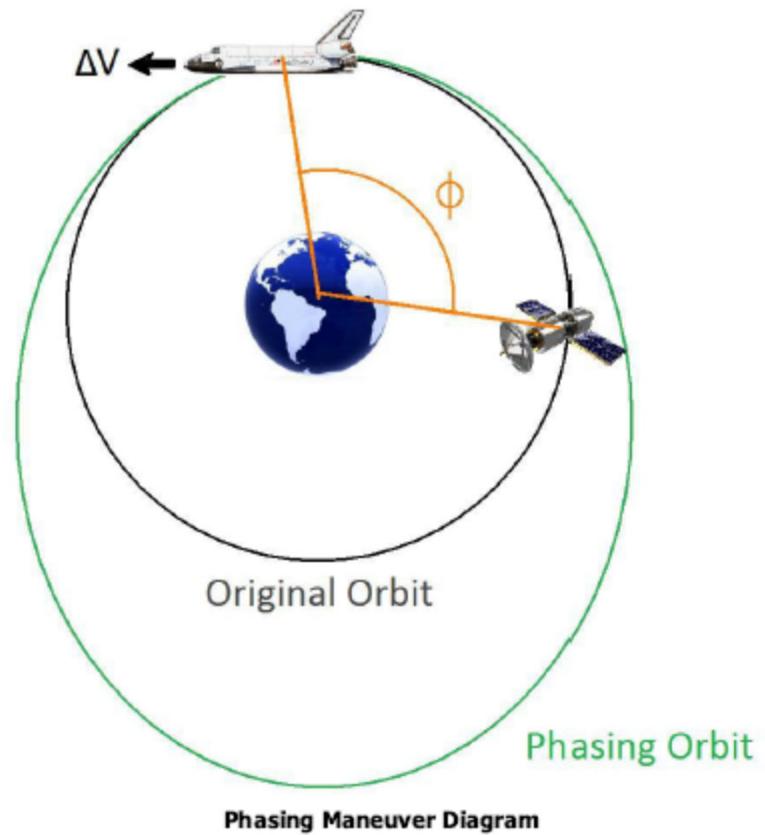

Phasing maneuvers are performed to change the **size of the original orbit** for a few periods in order to **meet back the original orbit at a different point in time**.

In this sense, the phasing maneuver has two burns and thus can be categorized as a two-impulse Hohmann transfer **from and back to the same orbit**. The first burn occurs at the original orbit. This shrinks or expands the orbit from its original state. Once the spacecraft completes the **transfer orbit** and returns to its original burn point, it then performs its second maneuver to coincide with its original orbit.

There are several utilities for phasing maneuvers.

**1-** If the main spacecraft needs to rendezvous with another spacecraft behind it, it would increase its period just enough to intercept the other spacecraft.

For example as shown in the picture, the space shuttle uses a phasing maneuver to rendezvous with a satellite that is  $\Phi$  degrees behind it.

# Phasing Maneuvers for Rendezvous

**2-** If it is needed to catch up with another spacecraft ahead of it, the main spacecraft would slows down to decrease its period.

**3-** the Phasing maneuvers is also used for station keeping of GEO satellites (East-West correction) or to change their observation area . There are basically only a few steps in computation of the phasing maneuver:

## I. Determination of the phasing orbit Period, ( $\tau$ or $T$ ).

This is determined by computing how far ahead or behind the target is in time.

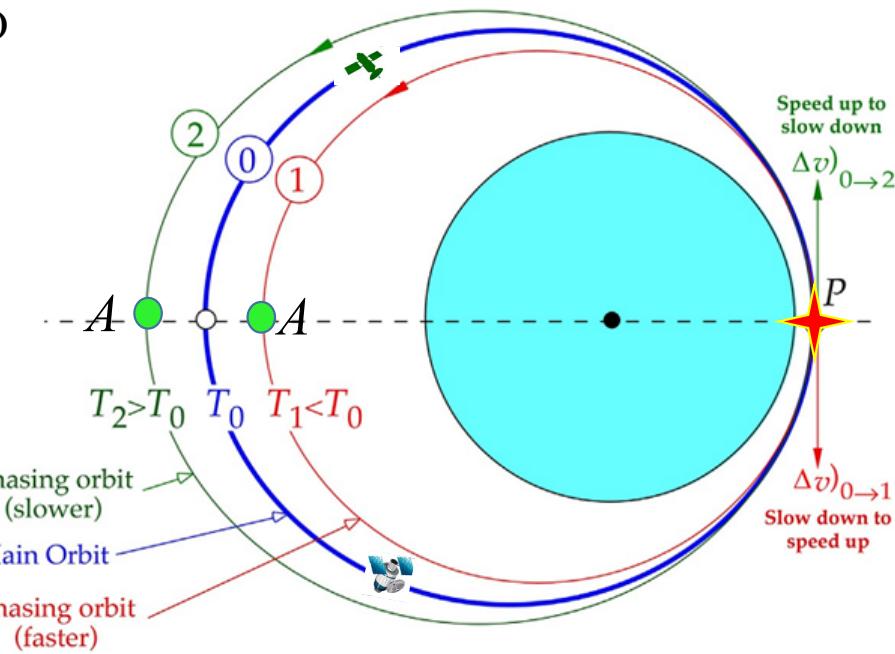

## II. Determined the SMA of the Phasing orbit, knowing $\tau$ .

$$a = \left( \frac{\tau \sqrt{\mu}}{2\pi} \right)^{2/3}$$

## III. Calculate the $\Delta v$ needed to perform the maneuver.

$$2a = r_P + r_A$$

$$h = \sqrt{2\mu} \sqrt{\frac{r_A r_P}{r_A + r_P}} \Rightarrow v_A; v_P$$

## Example 12

It is desired to shift the longitude of a GEO satellite  $12^\circ$  westward in three revolutions of its phasing orbit. Calculate the delta-v requirement.

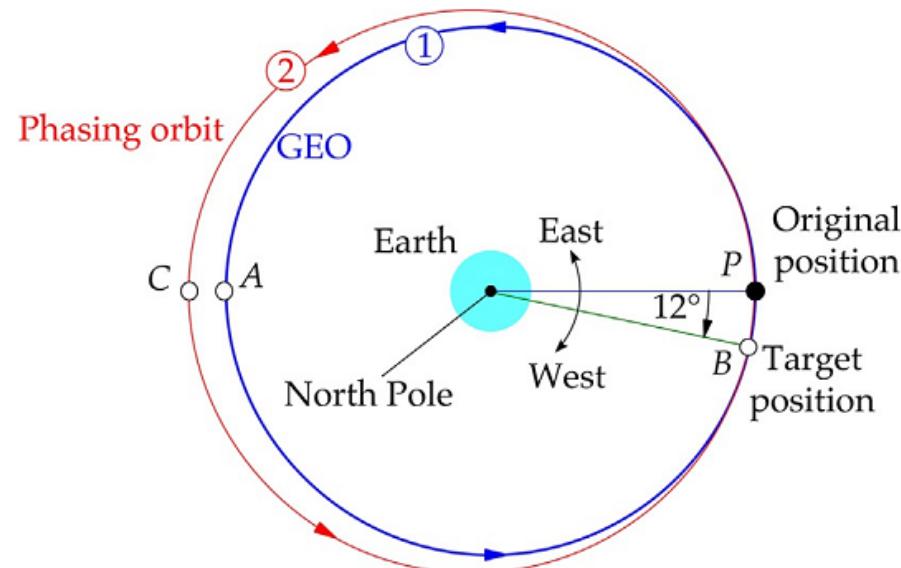

$$\omega_E = \omega_{\text{GEO}} = 72.922(10^{-6}) \text{ rad/s}$$

$$r_{\text{GEO}} = 42,164 \text{ km}$$

$$V_{\text{GEO}} = 3.0747 \text{ km/s}$$

$$\omega_E(3T_2) = 3 \cdot 2\pi + \Delta\Lambda$$

$$T_2 = \frac{1}{3} \frac{\Delta\Lambda + 6\pi}{\omega_E} = \frac{1}{3} \frac{12^\circ \cdot \frac{\pi}{180^\circ} + 6\pi}{72.922 \times 10^{-6}} = 87,121 \text{ s}$$

## Example 12

$$T_{\text{GEO}} = \frac{2\pi}{\omega_{\text{GEO}}} = 86,163 \text{ s}$$

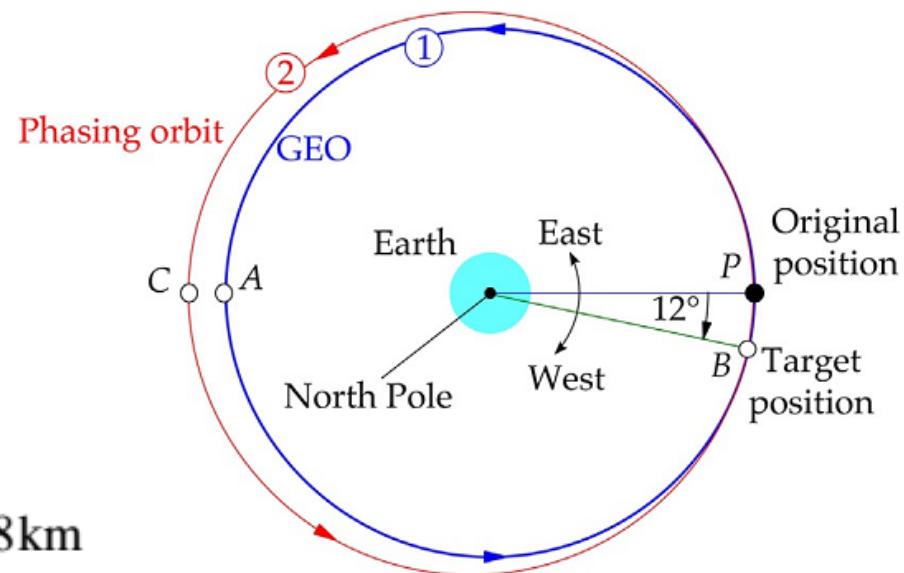

$$\dot{\Lambda} = \frac{\Delta\Lambda}{3T_2} = 8.0133 \times 10^{-7} \text{ rad/s} = 3.9669 \text{ degrees/day}$$

$$a_2 = \left( \frac{T_2 \sqrt{\mu}}{2\pi} \right)^{2/3} = \left( \frac{87,121 \sqrt{398,600}}{2\pi} \right)^{2/3} = 42,476 \text{ km}$$

$$2a_2 = r_p + r_C \Rightarrow r_C = 2 \cdot 42,476 - 42,164 = 42,788 \text{ km}$$

$$h_2 = \sqrt{2\mu} \sqrt{\frac{r_B r_C}{r_B + r_C}} = \sqrt{2 \cdot 398,600} \sqrt{\frac{42,164 \cdot 42,748}{42,164 + 42,788}} = 130,120 \text{ km}^2/\text{s}$$

$$v_P)_2 = \frac{130,120}{42,164} = 3.0859 \text{ km/s}$$

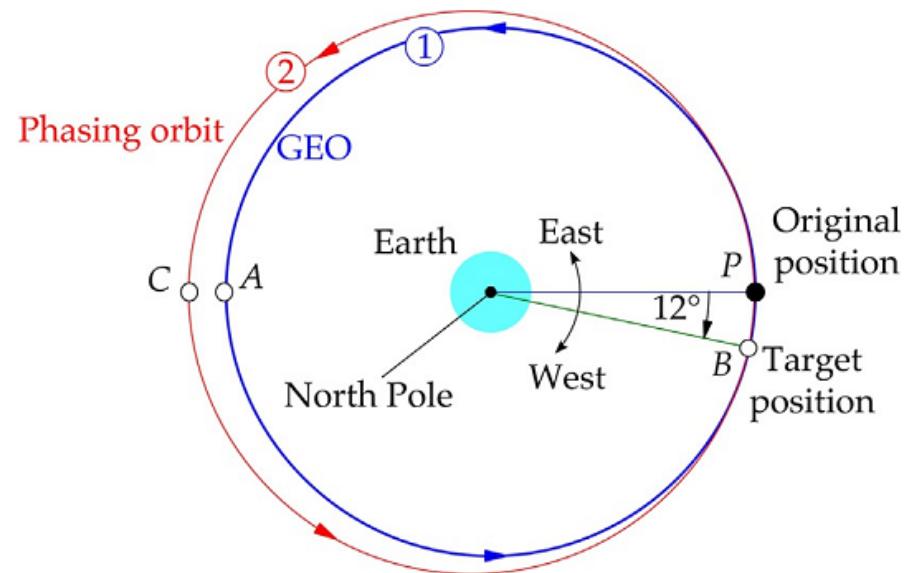

## Example 12

$$\Delta v = v_P)_2 - v_{\text{GEO}} = 3.0859 - 3.0747 = 0.01126 \text{ km/s}$$

$$\Delta v = v_{\text{GEO}} - v_P)_2 = 3.0747 - 3.08597 = -0.01126 \text{ km/s}$$

$$\Delta v_{\text{total}} = |0.01126| + |-0.01126| = \boxed{0.02252 \text{ km/s}}$$

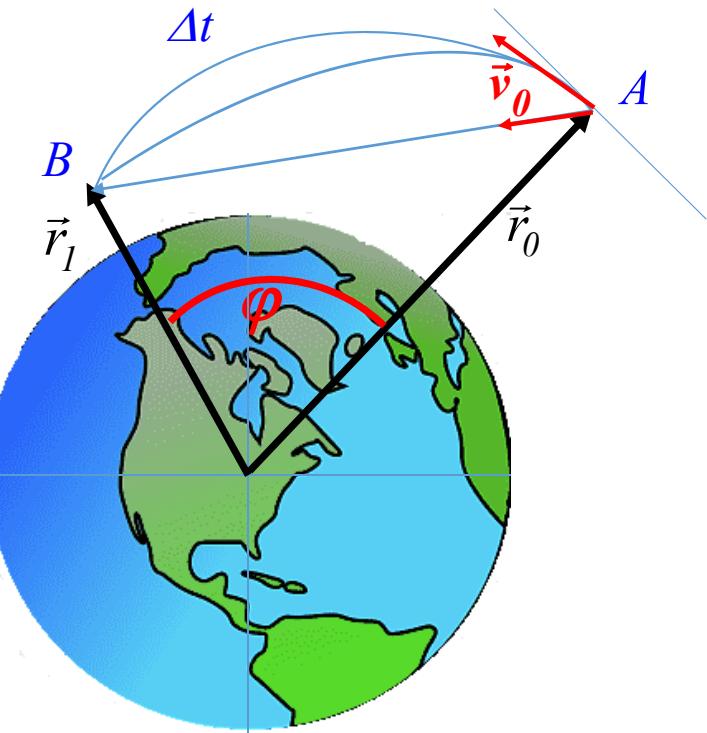

# Chasing Maneuver and the Lambert Problem

Occasionally we are interested to know how we can have a **ballistic** flight from point A to point B in space in a given or specified time. The Lambert's problem addresses this issue.

**Problem Statement:** Determine the initial **required** velocity,  $\vec{v}_0$  at  $\vec{r}_0$ , such that the space vehicle can have a ballistic trajectory to  $\vec{r}_1$  in a specified time interval  $\Delta t$  over a specific **range parameter** denoted by  $\varphi$ .

$$v_0 = \sqrt{\frac{\mu(1 - \cos \varphi)}{r_0 \cos \gamma_0 \left[ \frac{r_0 \cos \gamma_0}{r_1} - \cos(\varphi + \gamma_0) \right]}}$$

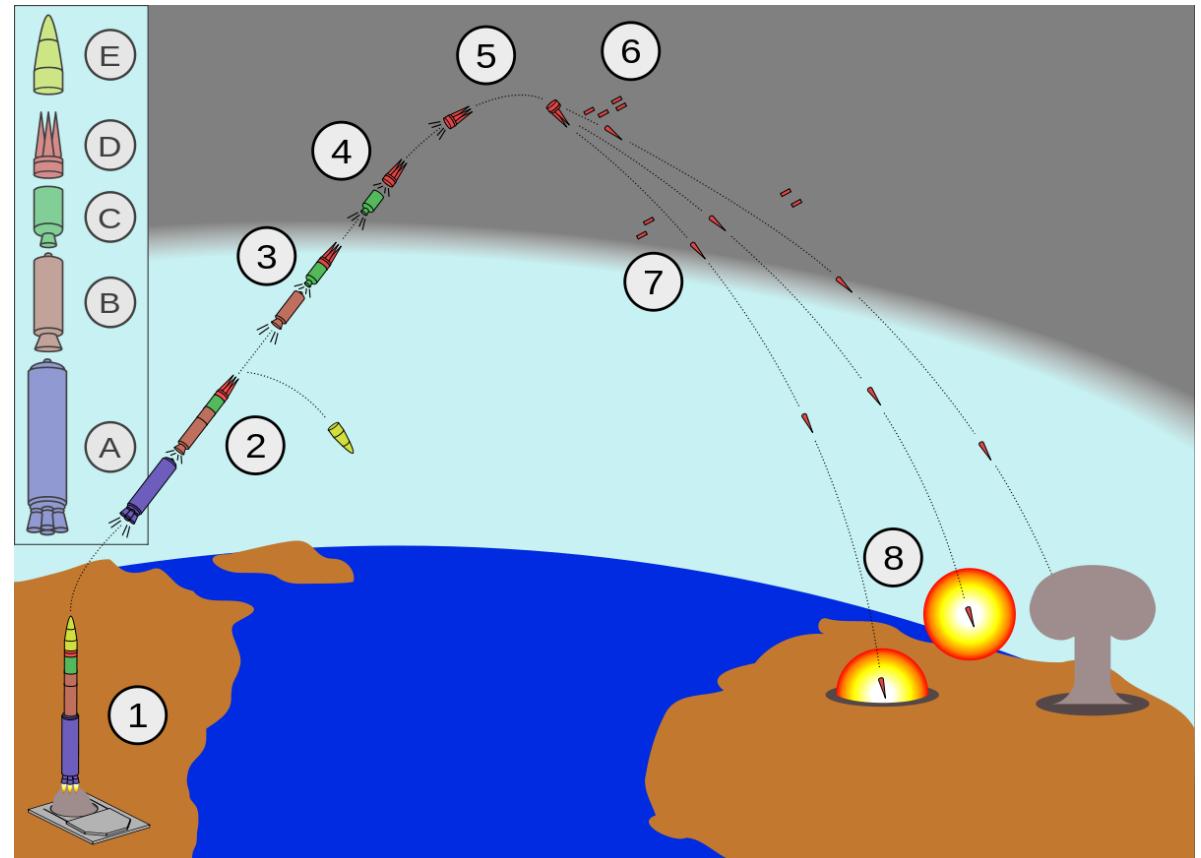

$$\Delta t = g(r_0, r_1, \varphi, \gamma_0)$$

**Note:** In fact if the time of flight was not an issue, we could have **various ballistic trajectories** to reach the target vector via different initial speed and initial flight path angle. In other words :

$$v_0 = f(r_0, r_1, \varphi, \gamma_0)$$

# Various applications of ballistic Trajectories

# Various applications of ballistic Trajectories

---

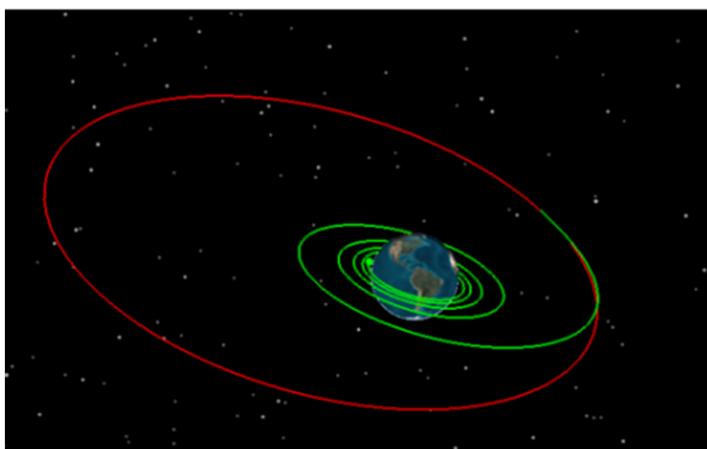

# Governing EOM for Continuous Thrust Non-Impulsive Orbital Maneuvers

$$\ddot{\mathbf{r}} = -\mu \frac{\mathbf{r}}{r^3} + \frac{\mathbf{F}}{m}$$

$$\ddot{\mathbf{r}} = -\mu \frac{\mathbf{r}}{r^3} + \frac{T}{m} \frac{\mathbf{v}}{v} \quad (\mathbf{v} = \dot{\mathbf{r}})$$

$$\frac{dm}{dt} = -\frac{T}{I_{sp} g_0}$$

*Accelerated Trajectories need a guidance law*

$$\vec{y} = \begin{Bmatrix} x \\ y \\ z \\ \dot{x} \\ \dot{y} \\ \dot{z} \\ m \end{Bmatrix} = \begin{Bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \\ y_7 \end{Bmatrix} \Rightarrow \dot{y} = \begin{Bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \\ \ddot{x} \\ \ddot{y} \\ \ddot{z} \\ \dot{m} \end{Bmatrix} = \begin{Bmatrix} y_4 \\ y_5 \\ y_6 \\ -\mu \frac{y_1}{r^3} + \frac{T}{m} \frac{y_4}{v} \\ -\mu \frac{y_2}{r^3} + \frac{T}{m} \frac{y_5}{v} \\ -\mu \frac{y_3}{r^3} + \frac{T}{m} \frac{y_6}{v} \\ -\frac{T}{I_{sp} g_0} \end{Bmatrix}$$

**Q-Guidance:** A simple guidance strategy is to apply acceleration (i.e. engine thrust) in the direction of  $V_{TBG}$  that is the **velocity to be gained**.

$$V_{TBG} = V_{Lambert} - V$$

# Crew exploration vehicle docking with ISS

---

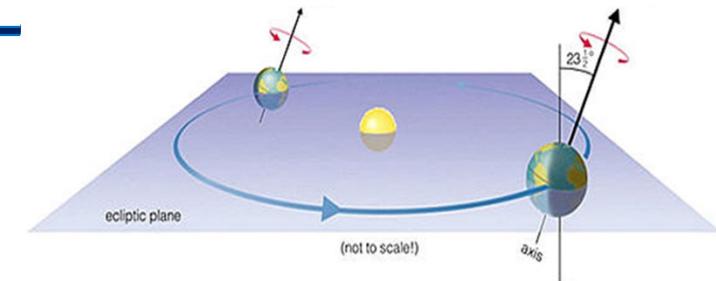

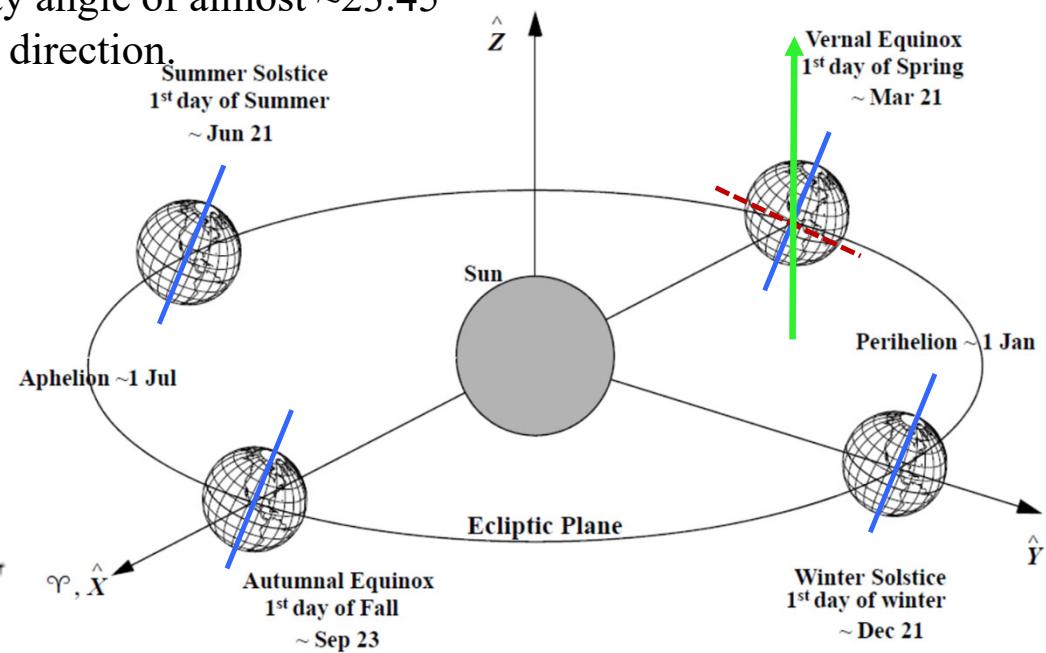

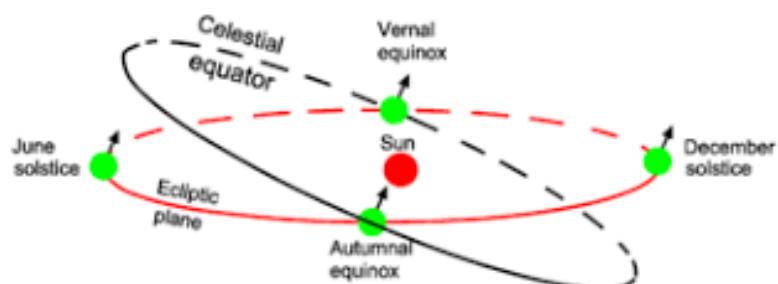

# Coordinate Systems

We need coordinate systems to describe and quantify motions.

Basic laws of motion are valid in an Inertial Coordinate System.

Earth revolves around the Sun:

- In the Ecliptic Plane,
- Earth axis of rotation has an Obliquity angle of almost  $\sim 23.45^\circ$
- Vernal Equinox (V.E.) is a reference direction.

# Key Reference Coordinate Systems

## I. HRF (Heliocentric Reference Frame), Inertial

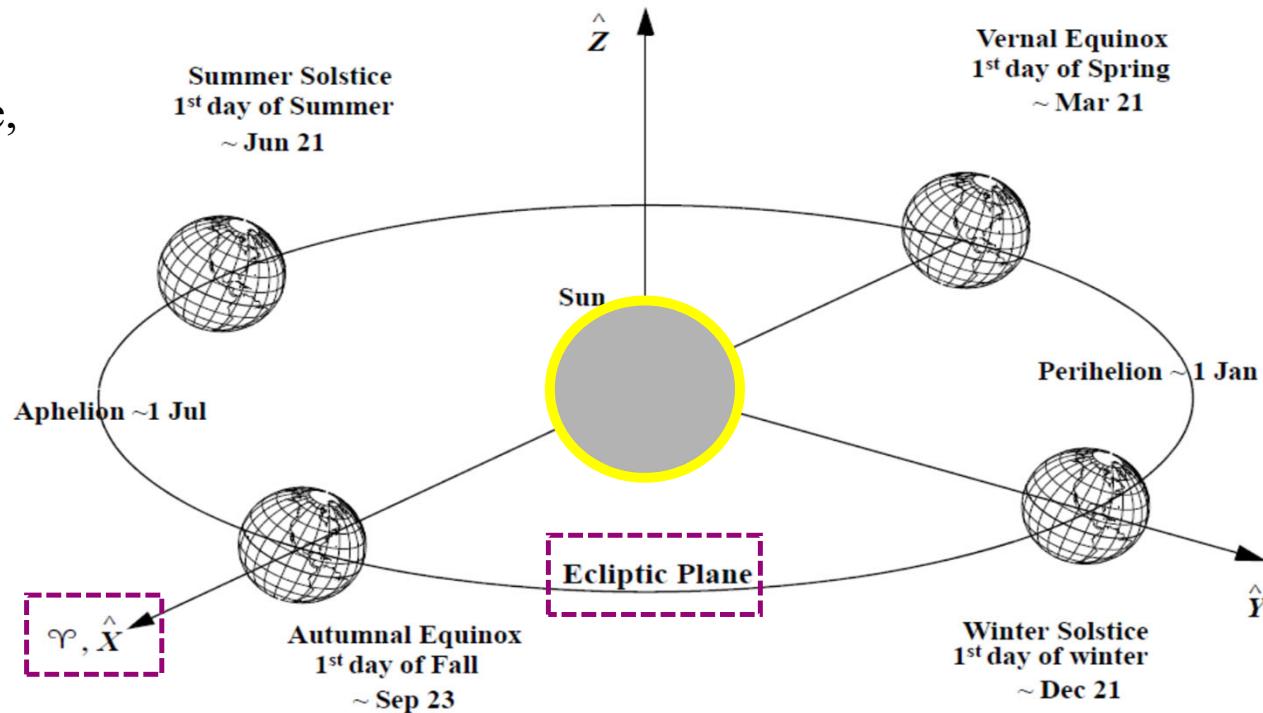

Origin: Sun center,

Fundamental plane: The Ecliptic plane,

Preferred direction: V.E.

Aries constellation  
symbol for ram horn

**Vernal equinox (V.E.)**, there are two moments in the year when the [Sun](#) is exactly above the [Equator](#) and day and night are of equal length. On one of these moments, the line connecting the Earth (intersection of the [ecliptic](#) with the Earth equator) to Sun points toward a Celestial direction that was initially towards the Aries constellation.

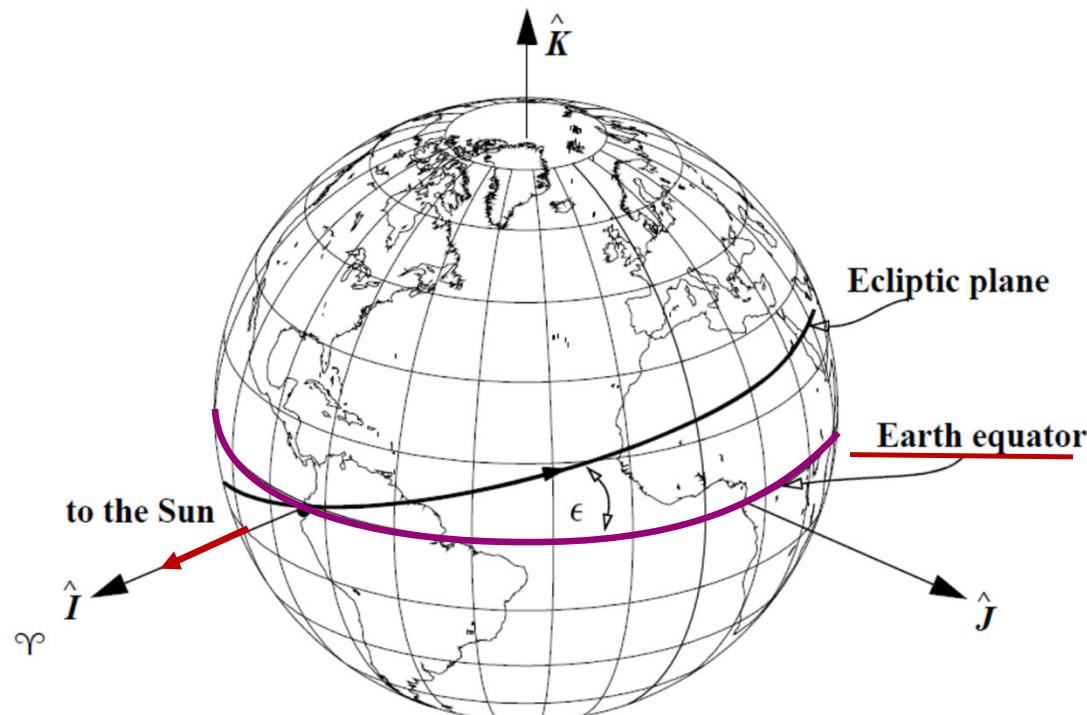

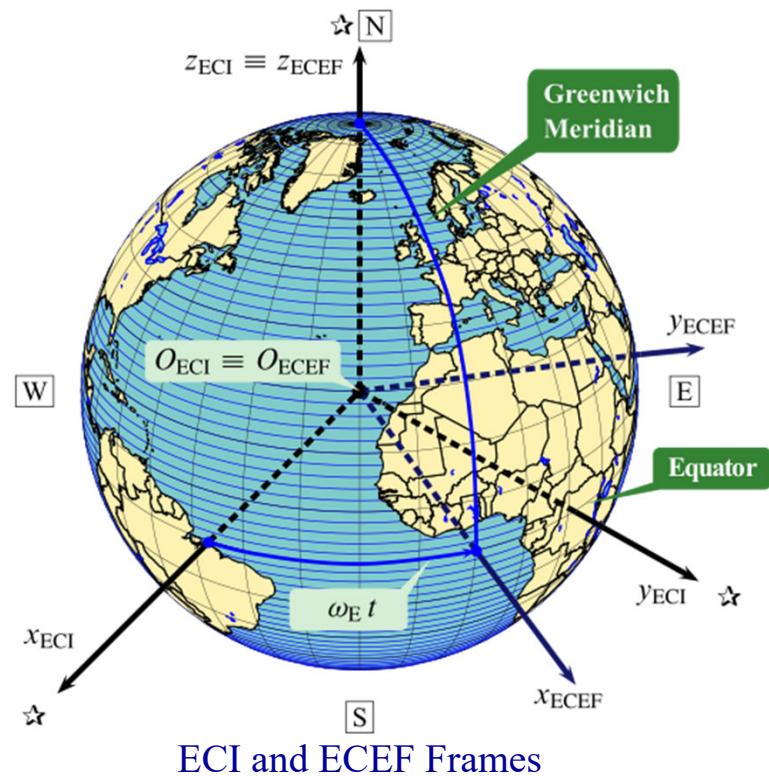

# Key Reference Coordinate Systems

## II. ECI (Earth Centered Inertial)

Origin: Earth center

Fundamental plane: Equatorial plane,

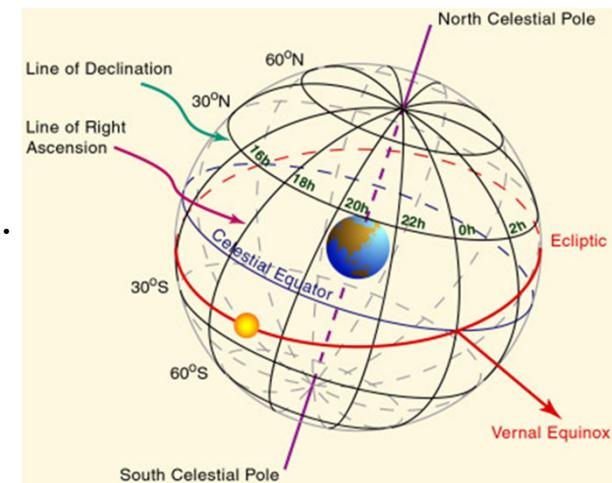

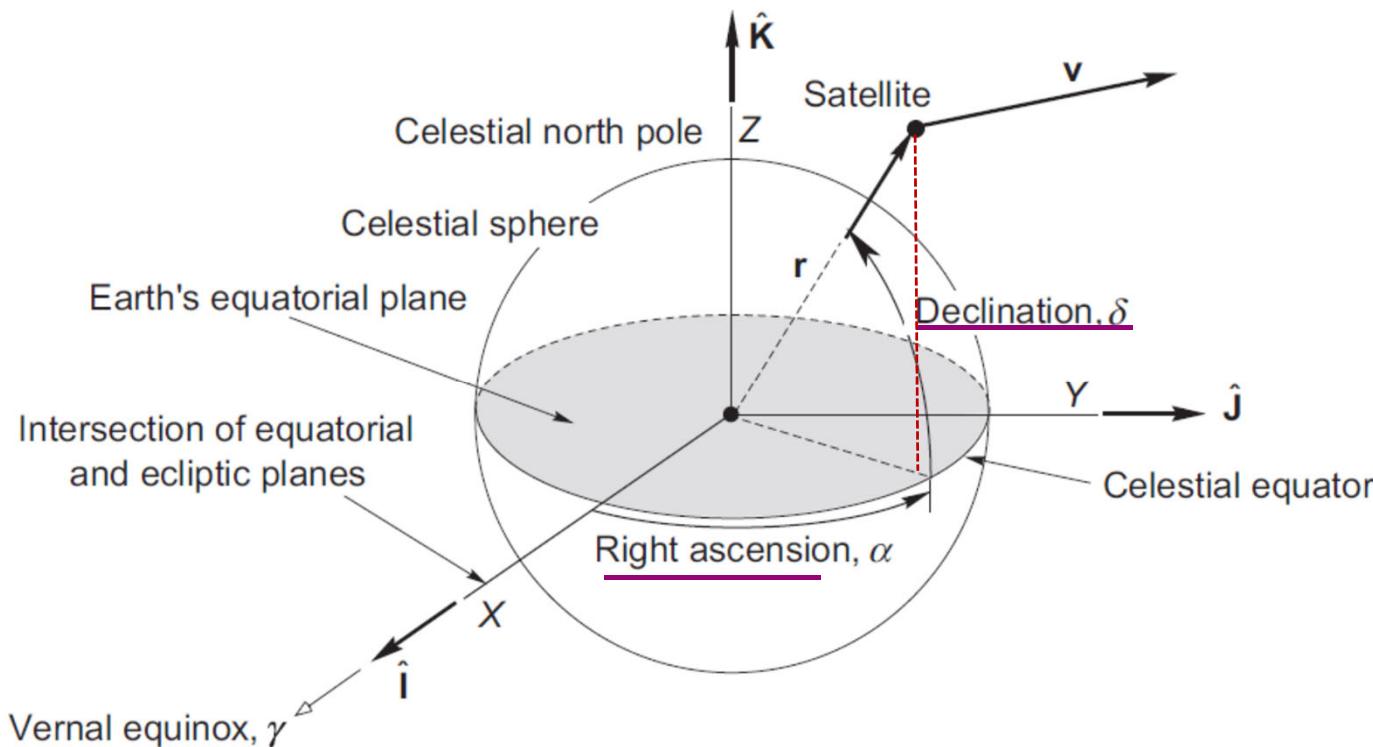

Preferred direction: V.E.

# Key Reference Coordinate Systems

## III-Celestial Sphere or Geocentric Equatorial CS (Inertial)

Points in this system are coordinated via right ascension and declination.

$$\mathbf{r}_{ECI} = X\hat{\mathbf{i}} + Y\hat{\mathbf{j}} + Z\hat{\mathbf{k}}$$

$$\mathbf{r}_{ECI} = r\hat{\mathbf{u}}_r$$

$$\begin{aligned}\hat{\mathbf{u}}_r &= \hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}} \\ &= \cos \delta \cos \alpha \hat{\mathbf{i}} \\ &\quad + \cos \delta \sin \alpha \hat{\mathbf{j}} \\ &\quad + \sin \delta \hat{\mathbf{k}}\end{aligned}$$

In astronomy the **celestial sphere** is a fictitious **sphere** of infinite radius centered at the Earth. All objects in the sky can be conceived as being projected upon the inner surface of the **celestial sphere**. In astronomy and celestial navigation, ephemeris is used to indicate the trajectory (coordinates) of objects in CS with time.

# Key Reference Coordinate Systems

## Example 13

Given  $\vec{r}_{ECI} = X\hat{I} + Y\hat{J} + Z\hat{K}$ , compute  $\alpha, \delta$ ?

$$1. r = \sqrt{X^2 + Y^2 + Z^2}; \quad 2. l = \frac{X}{r} \quad m = \frac{Y}{r} \quad n = \frac{Z}{r}$$

$$3. \hat{u}_r = l\hat{I} + m\hat{J} + n\hat{K} = \cos \delta \cos \alpha \hat{I} + \cos \delta \sin \alpha \hat{J} + \sin \delta \hat{K}$$

$$4. \delta = \sin^{-1} n; \quad -90^\circ \leq \delta \leq 90^\circ$$

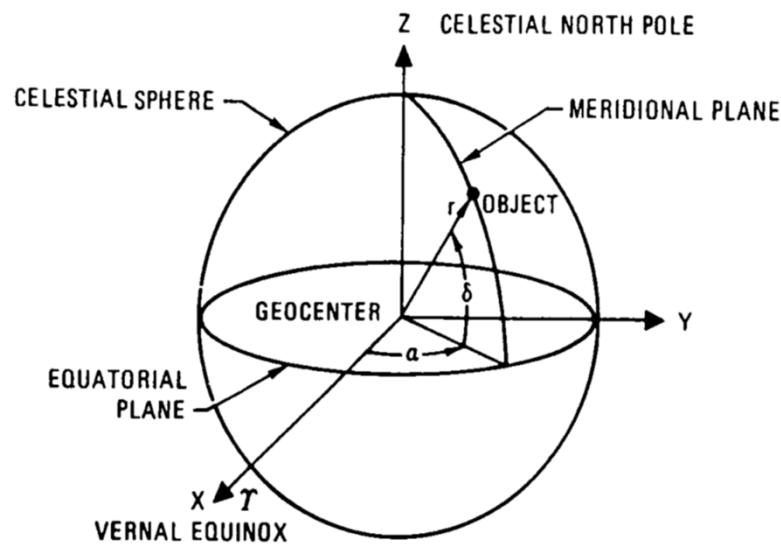

$$5. \alpha = \begin{cases} \cos^{-1} \left( \frac{l}{\cos \delta} \right) & m > 0 \\ 360^\circ - \cos^{-1} \left( \frac{l}{\cos \delta} \right) & m \leq 0 \end{cases}; \quad 0^\circ \leq \alpha \leq 360^\circ$$

Example:  $\vec{r} = -5368\hat{I} - 1784\hat{J} + 3941\hat{K}$ ; Km  $\Rightarrow r = 6574$  Km

$$\hat{u}_r = -0.7947\hat{I} - 0.2642\hat{J} + 0.5464\hat{K}$$

$$\delta = \sin^{-1} n = \sin^{-1} 0.5464 \Rightarrow \delta = 33.12^\circ$$

$$\alpha = 360^\circ - \cos^{-1} \left( \frac{l}{\cos \delta} \right) = 198.4^\circ$$

# Key Reference Coordinate Systems

## More About the Sun orbit within the Celestial Sphere

**Vernal Equinox (V.E.):** Ascending node: 21 March

**Autumnal Equinox:** Descending Node: 23 Sep.

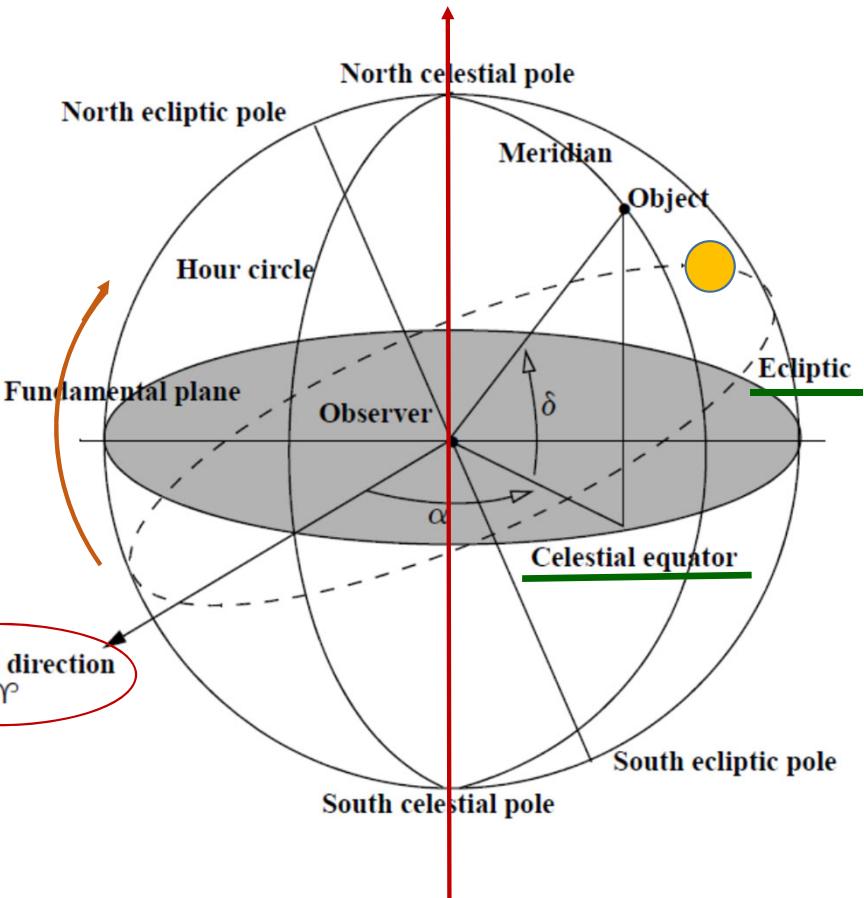

**Another definition for V.E. as a reference axis:**

1-It occurs when the Sun's declination is zero as it changes from negative to positive values.

2-Thus the Sun position can be approximated around the Earth for simulation purposes or its effect on satellites depending on a special calendar called the Julian date.

3-From the point of view of the celestial sphere, the sun follows an orbit over the course of a year on the ecliptic.

Its orbit is tilted 23.5° with respect to the celestial equator.

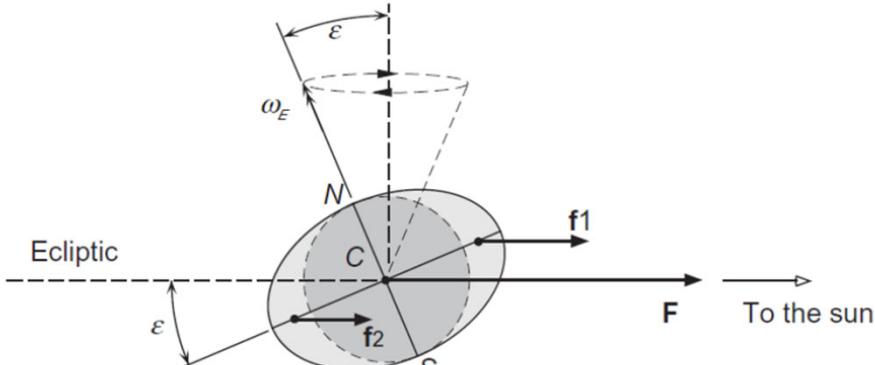

# Precession and Nutation

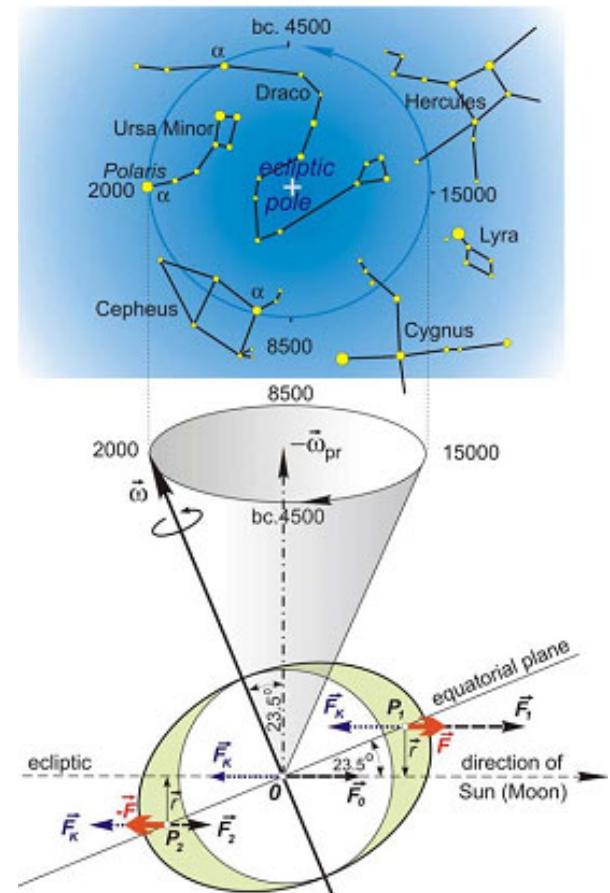

Unfortunately due to a number of factors the V.E in not really a fixed celestial direction. These include : the effect of the Sun and the Moons pull as well as the non-spherical not homogeneous natural shape of the Earth. Equinox location is function of time (Julian date).

- Sun and Moon interact with Earth oblateness to produce

- Precession of equinox
- Nutation

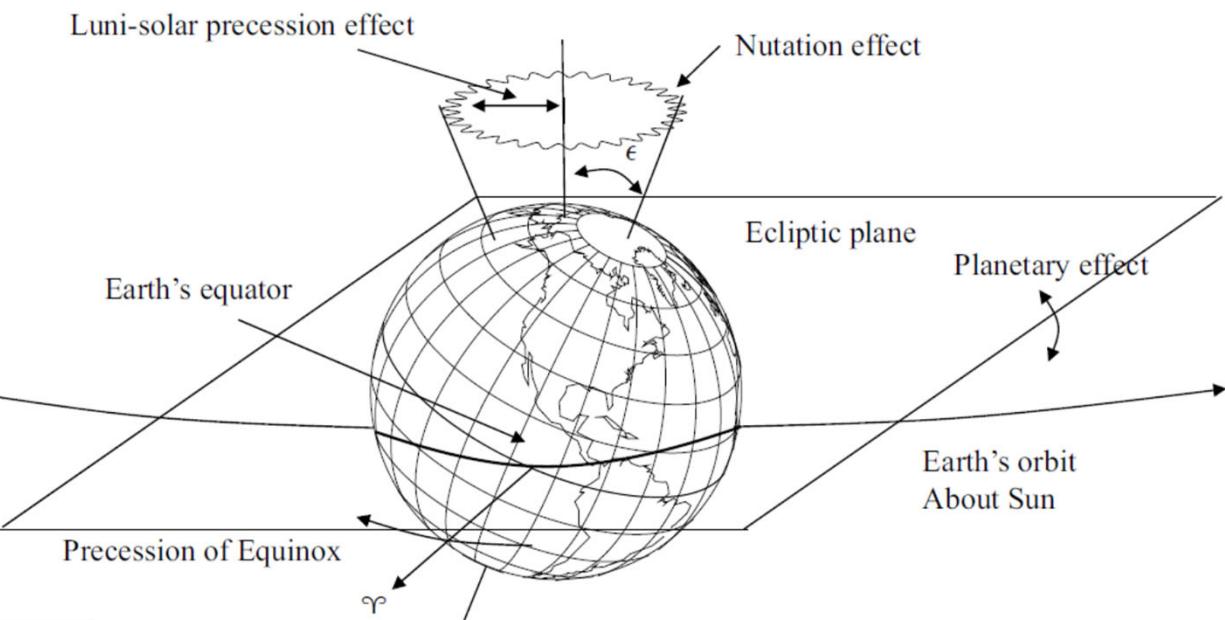

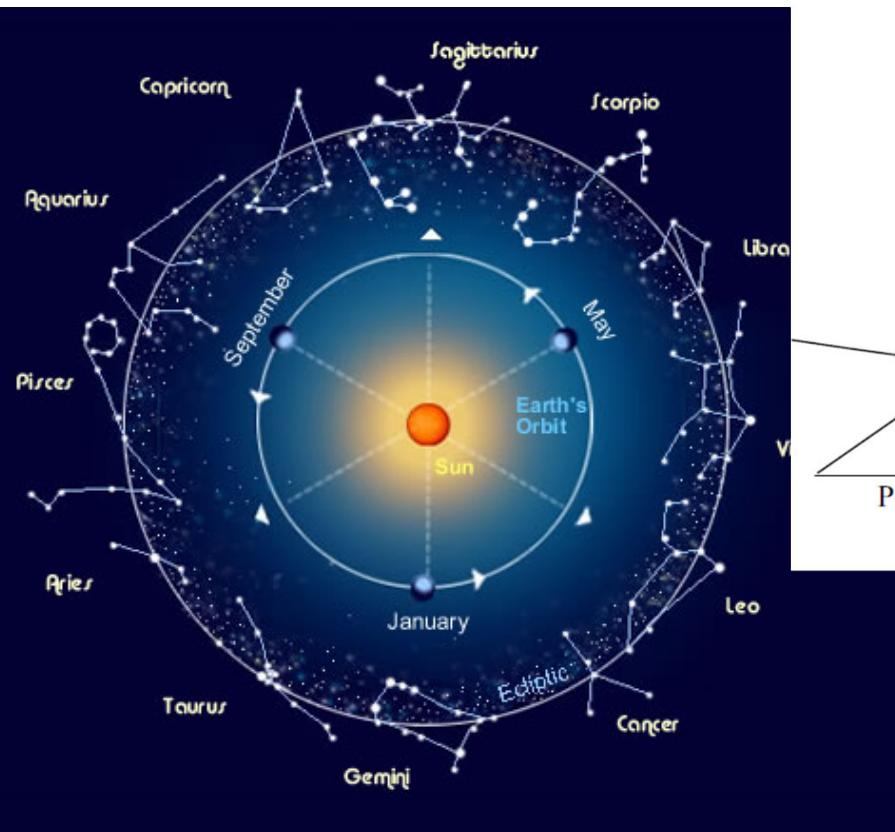

- ➡  Gyroscopic Precession
- ➡  Earth Precession

# Precession and Nutation

Therefor there are two motions ( Precession and Nutation of different amplitude and frequency) imposed on the direction of the Earth rotation axis , that in fact cause the Equinox Motion to be a function of time.

## Precession:

Amplitude : 23.5  
Period: 26000 Years  
Approximately 1.4Deg per century.

## Nutation:

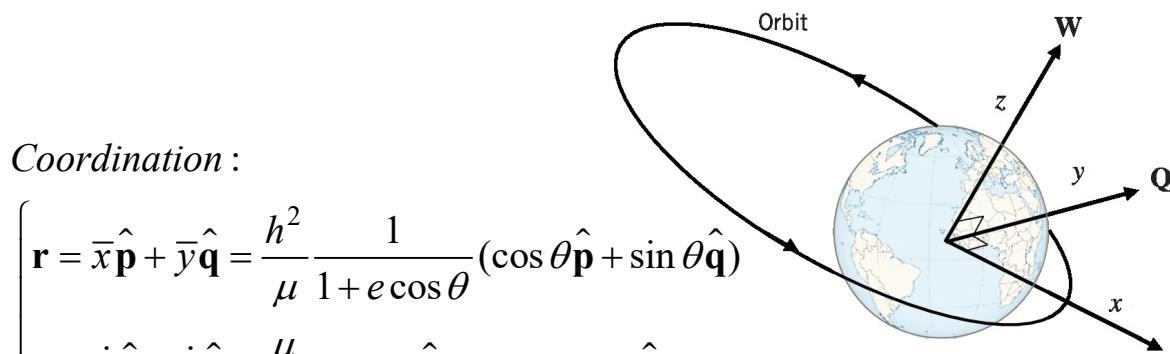

Amplitude :0.0025  
Period: 18.6 Years

# Key Reference Coordinate Systems

## IV- Perifocal Coordinate Frame , Inertial

Origin: Earth Center

Fundamental plane: The Orbital Plane,  
preferred direction: Perigee (Eccentricity Vector)

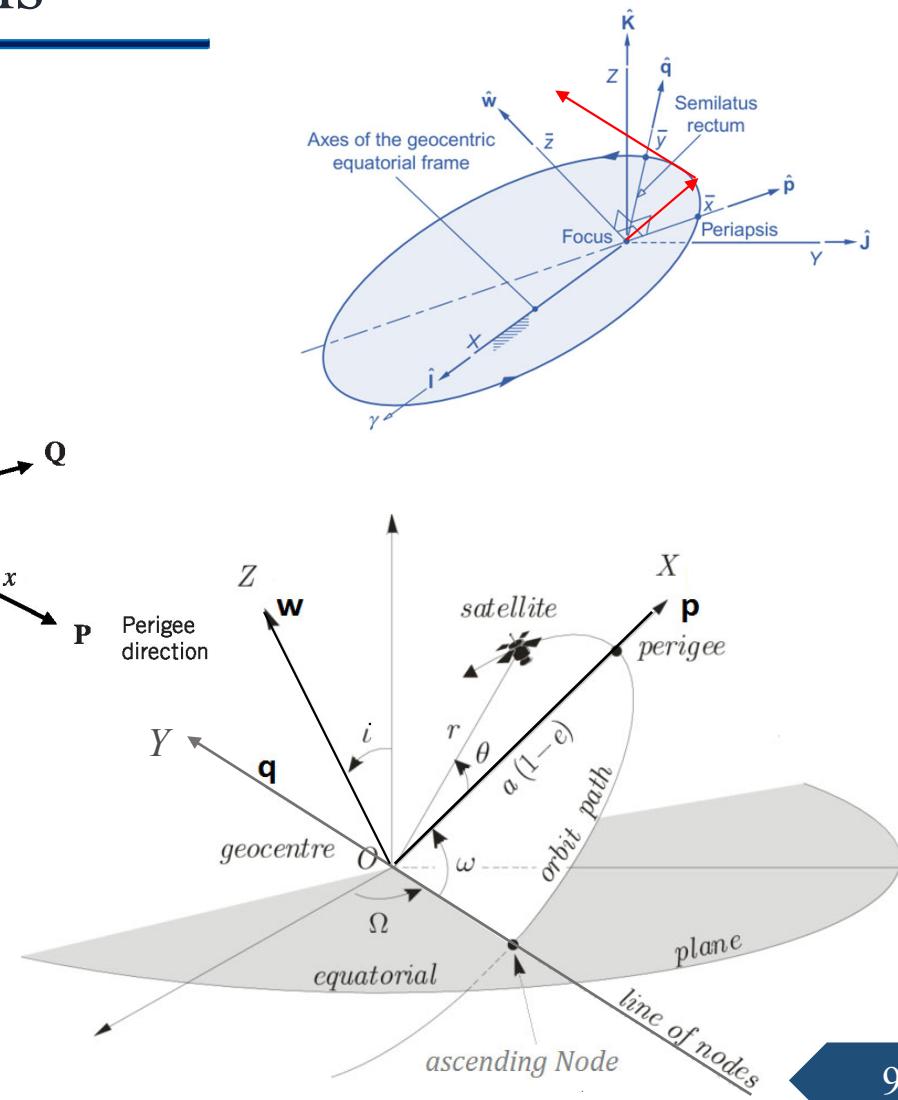

Coordination :

$$\mathbf{r} = \bar{x}\hat{\mathbf{p}} + \bar{y}\hat{\mathbf{q}} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} (\cos\theta\hat{\mathbf{p}} + \sin\theta\hat{\mathbf{q}})$$

$$\mathbf{v} = \dot{\bar{x}}\hat{\mathbf{p}} + \dot{\bar{y}}\hat{\mathbf{q}} = \frac{\mu}{h} [-\sin\theta\hat{\mathbf{p}} + (e + \cos\theta)\hat{\mathbf{q}}]$$

$$\rightarrow \begin{cases} \{\mathbf{r}\}_{\bar{x}} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} \begin{pmatrix} \cos\theta \\ \sin\theta \\ 0 \end{pmatrix} \\ \{\mathbf{v}\}_{\bar{x}} = \frac{\mu}{h} \begin{pmatrix} -\sin\theta \\ e + \cos\theta \\ 0 \end{pmatrix} \end{cases}$$

# Key Reference Coordinate Systems

## V- Earth-Centered Earth-Fixed Frame (ECEF), Non-Inertial

Origin: Earth center

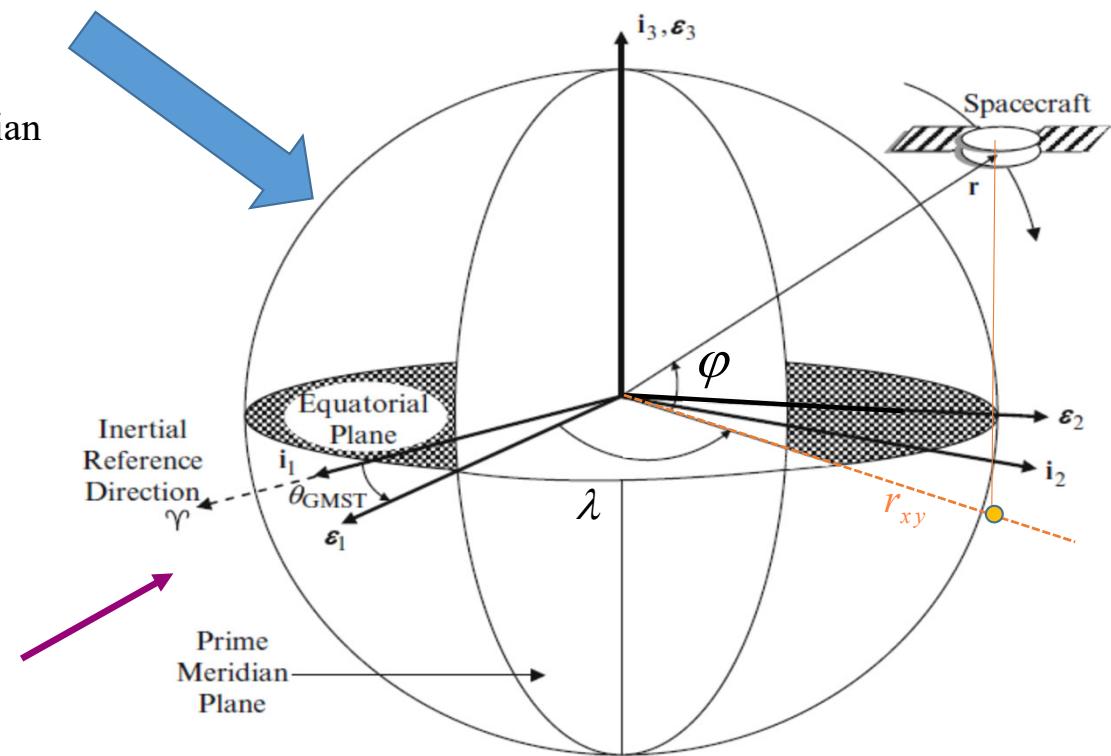

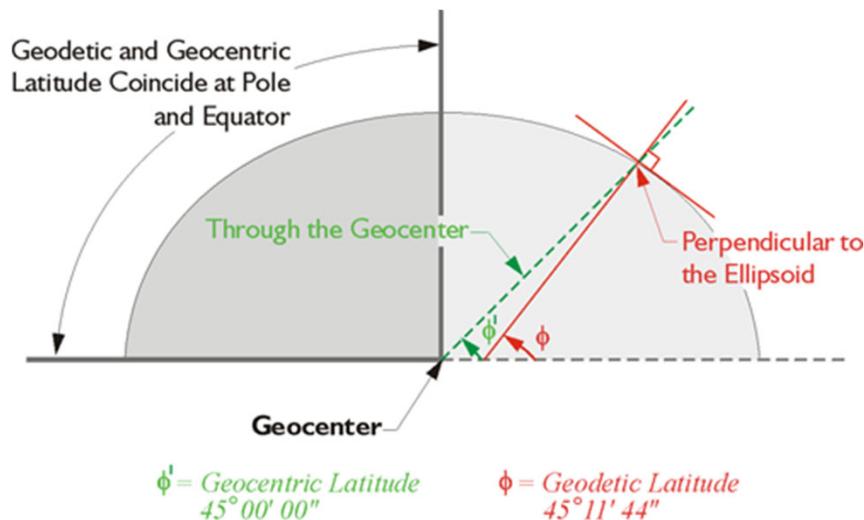

Fundamental plane: Equatorial plane,

Preferred direction: Intersection of Greenwich meridian

With the Equator

**Coordinates:**

- Longitude ( $\lambda$ ),
- Latitude ( $\varphi_{gc}$  or  $\varphi_{gd}$ )

Greenwich Mean Sidereal Time ( $\theta_{GMST}$ ) is the hour angle of the average position of the vernal equinox, neglecting short term motions of the equinox due to nutation.

# Key Reference Coordinate Systems

- Shape of the Earth

  - Spherical

$$r = \begin{bmatrix} r \cos \varphi_{gc} \cos \lambda \\ r \cos \varphi_{gc} \sin \lambda \\ r \sin \varphi_{gc} \end{bmatrix}$$

  - Ellipsoid

$$r = \begin{bmatrix} (N + h_{ellp.}) \cos \varphi_{gd} \cos \lambda \\ (N + h_{ellp.}) \cos \varphi_{gd} \sin \lambda \\ (N(1 - e_E^2) + h_{ellp.}) \sin \varphi_{gd} \end{bmatrix}$$

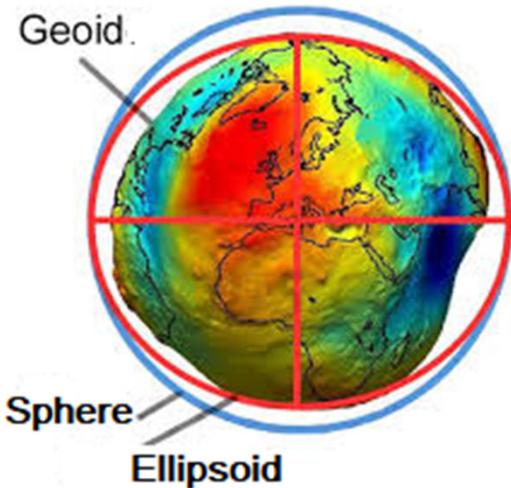

$$N = \frac{R_E}{\sqrt{1 - e_E^2 \sin^2 \varphi_{gd}}}; \quad h_{ellp.} = \frac{r_{xy}}{\cos(\varphi_i)} - N; \quad e_E \approx 0.08081$$

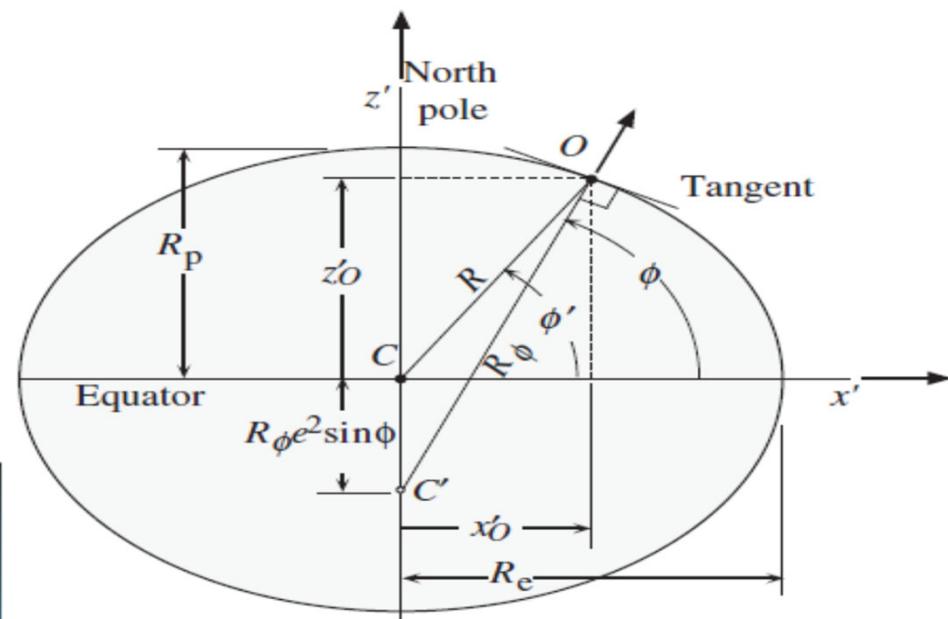

# Key Reference Coordinate Systems

## Shape of the Earth

$$\tan \varphi_{gd} = \frac{N + h_{ell}}{N(1 - e_E^2) + h_{ell}} \tan \varphi_{gc}$$

$$[\rho]^{ENU} = \rho \begin{bmatrix} \cos(el) \cos(\pi/2 - Az) \\ \cos(el) \sin(\pi/2 - Az) \\ \sin(el) \end{bmatrix}$$

# Orbital Elements and the State Vector Relation

**Orbital elements (OE)** are a collection of six parameters that can uniquely identify a specific orbit in terms of shape and orientation within the 3D space. Though , there are a different ways to mathematically describe the same orbit, but all schemes consist of a set of six parameters commonly used in astronomy and orbital mechanics. In reality due to gravitational perturbations by other celestial objects OE may change with time.

## Orbit Representation Methods:

1-Cartesian (Inertial) Coordinates, State vector notation

$$X = [\mathbf{r} \quad \mathbf{v}]^T$$

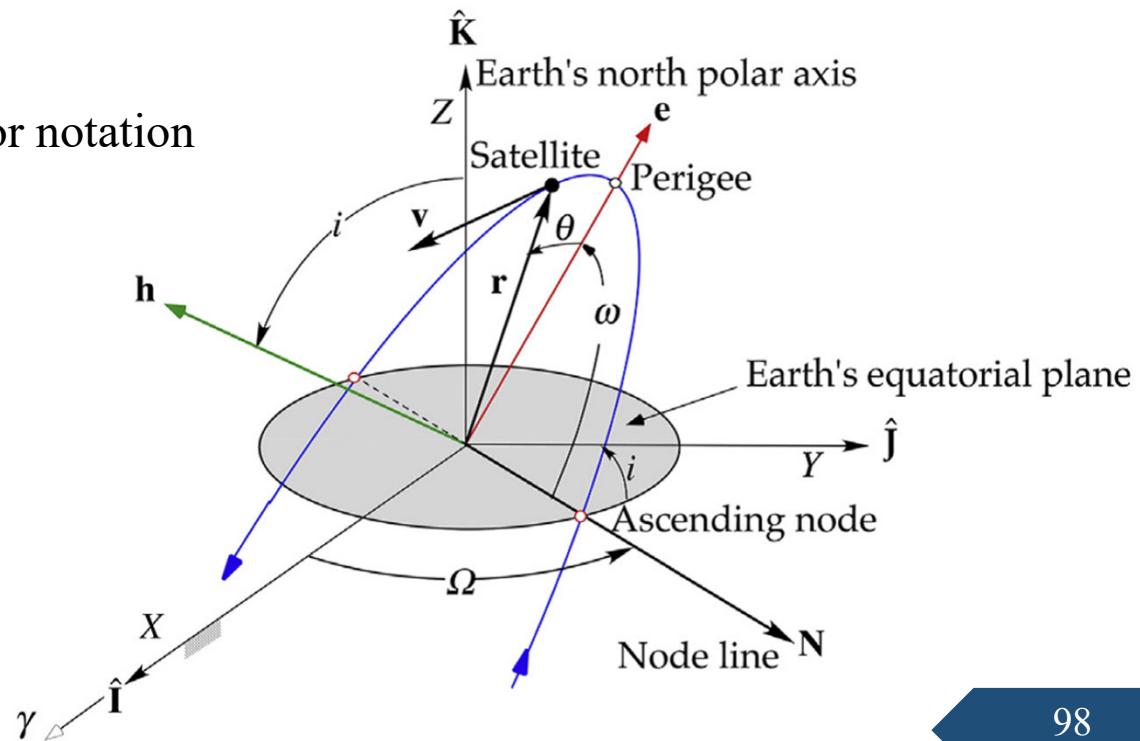

2-True Classical Orbital Elements

$$\alpha = [a \quad e \quad i \quad \Omega \quad \omega \quad t]^T$$

3-Modified Classical Element Set

$$\alpha = [a \quad e \quad i \quad \Omega \quad \omega \quad \theta]^T \text{ or}$$

$$\alpha = [h \quad e \quad i \quad \Omega \quad \omega \quad M]^T$$

# Orbital Elements and the State Vector Relation

OE and the satellite state vector are defined below, where we can do conversion between them as well.

$$\mathbf{r} = [X \quad Y \quad Z]^T, \mathbf{v} = [v_X \quad v_Y \quad v_Z]^T$$

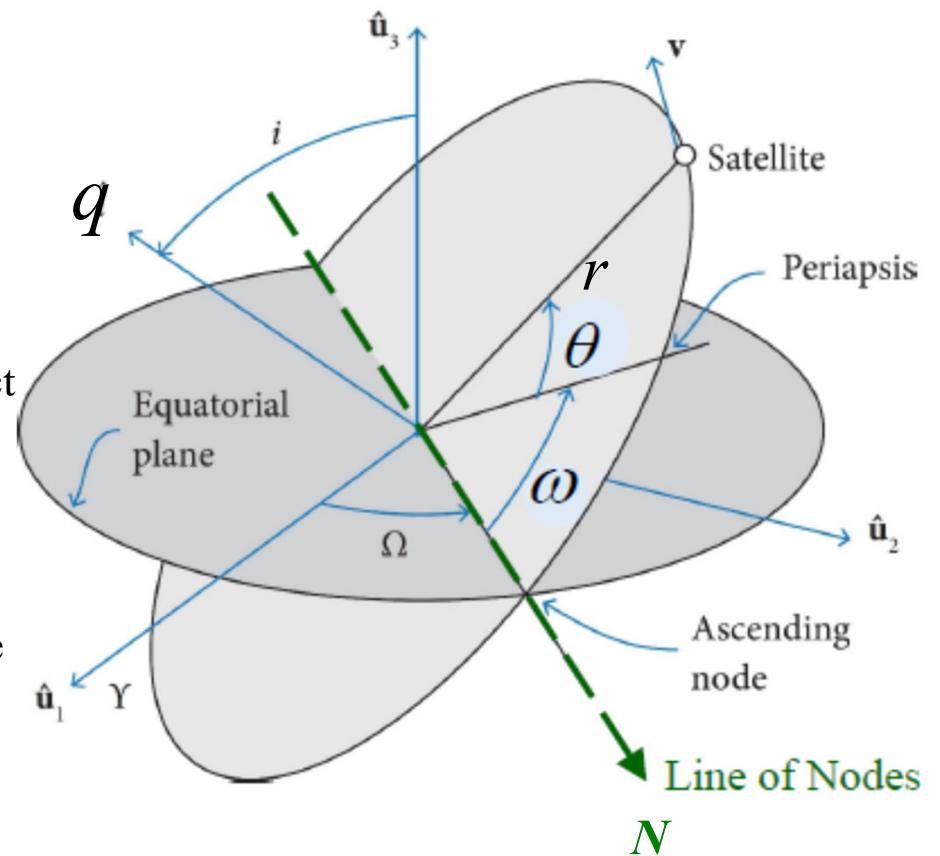

$$\alpha = [a \quad e \quad i \quad \Omega \quad \omega \quad \theta]^T$$

h or p Shape 3D Orientation Position, Reference time  
2D Size

**Inclination (*i*)** - vertical tilt of the orbital plane with respect to ellipse with respect to the reference (equatorial) plane.

**Longitude or Right ascension of the ascending node ( $\Omega$ )** - This angle is measured in the reference plane, and is the angle between the V.E. direction and the lines of nodes (LN). In turn the LN is the intersection of the orbital plane with the equatorial reference plane.

**Argument of periapsis or perigee ( $\omega$ )** – This angle defines the orientation of the ellipse in the orbital plane and is measure from the ascending node to the periapsis point of the orbit.

# State Vector to OE transformation Algorithm

State vector (SV) to Orbital elements (OE) transformation can be achieved via the following algorithms. Inverse transformation from OE to SV is also possible. The problem is defined as : Given the satellite SV, find its corresponding OE. The procedure is stated below.

*The satellite SV is usually given in ECI, as :*

$$\mathbf{r} = [X \ Y \ Z]^T, \mathbf{v} = [v_x \ v_y \ v_z]^T$$

*Find its corresponding OE,*

$$\alpha = [a \ e \ i \ \Omega \ \omega \ \theta]^T$$

$$1. \ r = \sqrt{\mathbf{r} \cdot \mathbf{r}} = \sqrt{X^2 + Y^2 + Z^2}$$

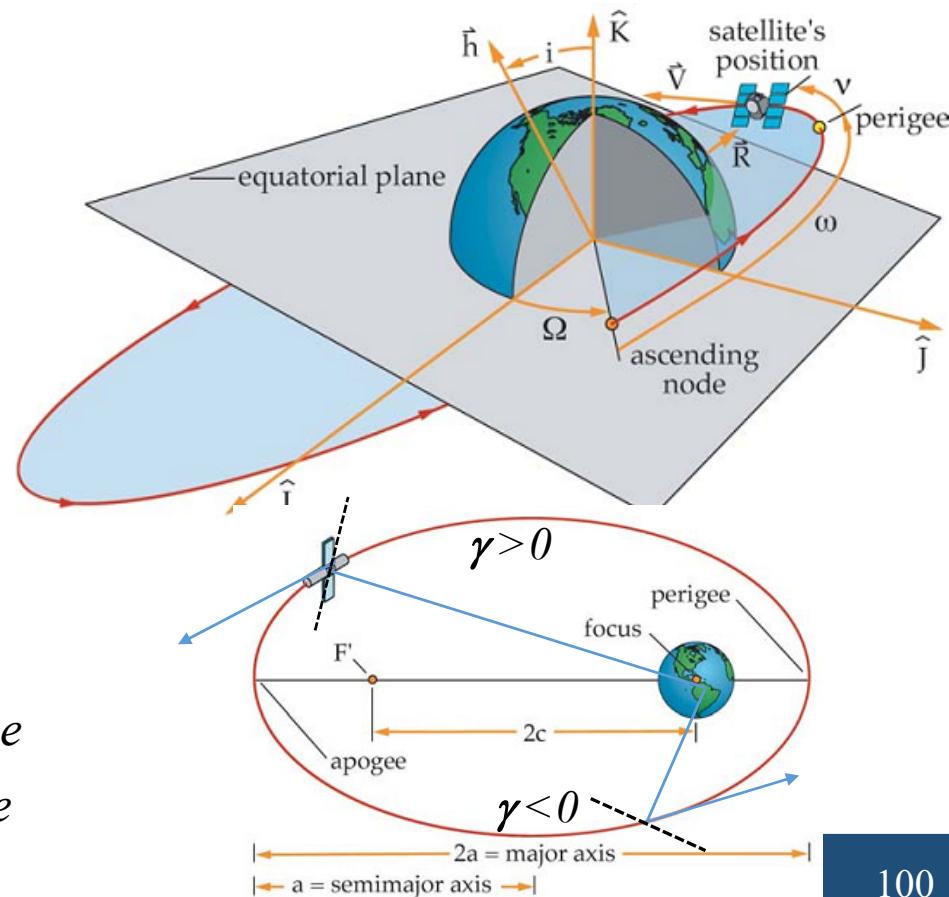

$$v = \sqrt{\mathbf{v} \cdot \mathbf{v}} = \sqrt{v_x^2 + v_y^2 + v_z^2}$$

$$v_r = \mathbf{r} \cdot \mathbf{v} / r = (Xv_x + Yv_y + Zv_z) / r = v \sin\gamma$$

Note that :  $\mathbf{r} \cdot \mathbf{v} = rv \cos\beta = rv \sin\gamma$

$\Rightarrow v_r > 0$  The satellite is moving away from the perigee

Or if  $v_r < 0$  The satellite is moving towards the perigee

# State Vector to OE transformation

$$2. \quad \mathbf{h} = \mathbf{r} \times \mathbf{v} ; h = \sqrt{\mathbf{h} \cdot \mathbf{h}} \rightarrow p = \frac{h^2}{\mu}$$

$$3. \quad \mathbf{h} \cdot \hat{\mathbf{K}} = h \cos i = h_z \Rightarrow i = \cos^{-1} \left( \frac{h_z}{h} \right)$$

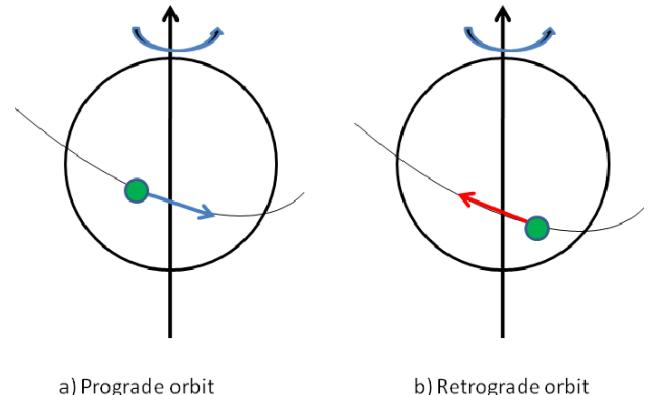

Note that :

$0 < i < 90^\circ \Rightarrow \text{Prograde Orbit}$  **Or**  $90^\circ < i < 180^\circ \Rightarrow \text{Retrograde Orbit}$

$$4. \quad \mathbf{N} = \hat{\mathbf{K}} \times \mathbf{h} = \begin{vmatrix} \hat{\mathbf{I}} & \hat{\mathbf{J}} & \hat{\mathbf{K}} \\ \mathbf{0} & \mathbf{0} & \mathbf{1} \\ h_x & h_y & h_z \end{vmatrix} ; N = \sqrt{\mathbf{N} \cdot \mathbf{N}}$$

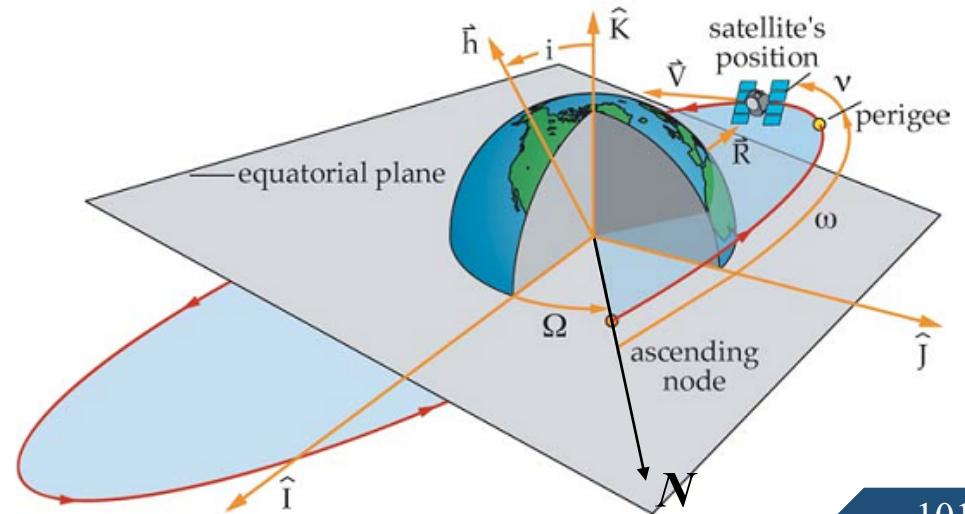

$$\mathbf{N} \cdot \hat{\mathbf{I}} = N \cos \Omega$$

$$5. \quad \Omega = \begin{cases} \cos^{-1} \left( \frac{N_x}{N} \right) & (N_y \geq 0) \\ 360^\circ - \cos^{-1} \left( \frac{N_x}{N} \right) & (N_y < 0) \end{cases}$$

a) Prograde orbit

b) Retrograde orbit

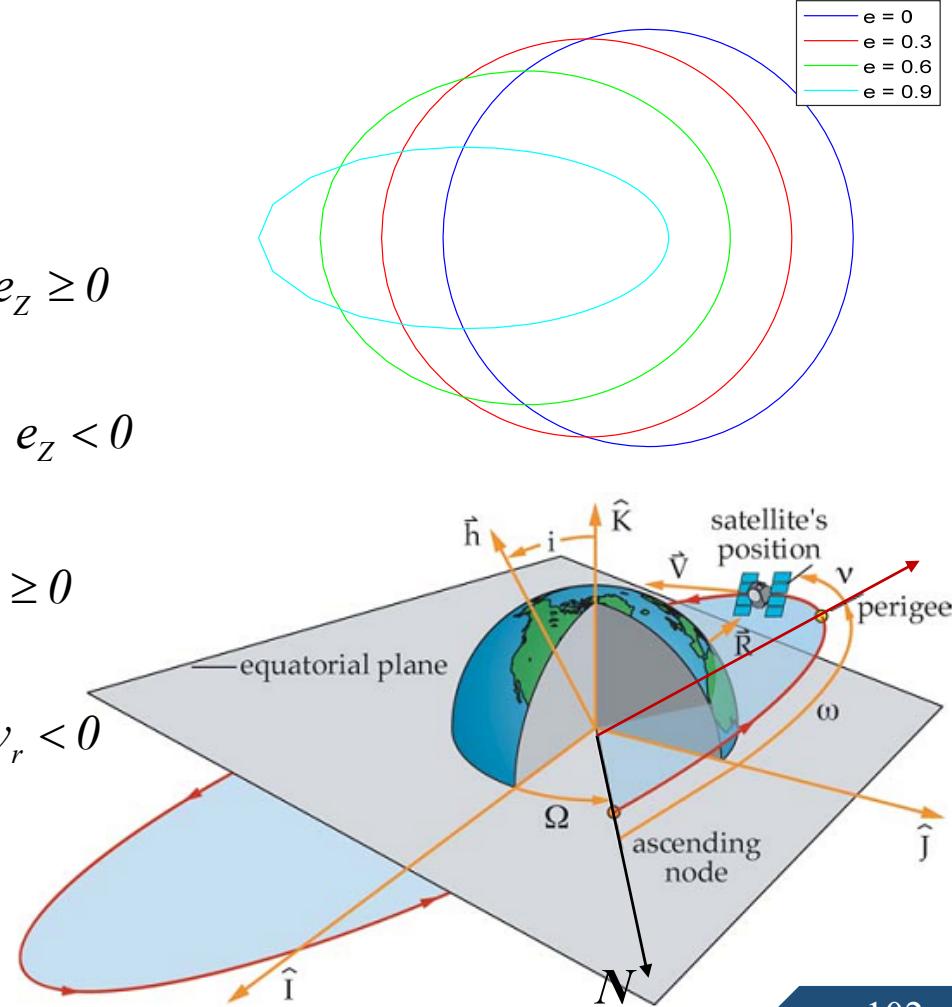

# State Vector to OE transformation

$$6. \quad \mathbf{e} = \frac{\mathbf{v} \times \mathbf{h}}{\mu} - \frac{\mathbf{r}}{r} = \frac{\mathbf{I}}{\mu} \left[ \left( v^2 - \frac{\mu}{r} \right) \mathbf{r} - r \mathbf{v}_r \mathbf{v} \right], e = \sqrt{\mathbf{e} \cdot \mathbf{e}}$$

$$7. \quad \mathbf{N} \cdot \mathbf{e} = N e \cos \omega \rightarrow \omega = \begin{cases} \cos^{-1} \left( \frac{\mathbf{N} \cdot \mathbf{e}}{Ne} \right) & \text{for } e_z \geq 0 \\ 360^\circ - \cos^{-1} \left( \frac{\mathbf{N} \cdot \mathbf{e}}{Ne} \right) & \text{for } e_z < 0 \end{cases}$$

$$8. \quad \mathbf{r} \cdot \mathbf{e} = r e \cos \theta \rightarrow \theta = \begin{cases} \cos^{-1} \left( \frac{\mathbf{e} \cdot \mathbf{r}}{er} \right) & \text{for } v_r \geq 0 \\ 360^\circ - \cos^{-1} \left( \frac{\mathbf{e} \cdot \mathbf{r}}{er} \right) & \text{for } v_r < 0 \end{cases}$$

$$\frac{v^2}{2} - \frac{\mu}{r} = -\frac{\mu}{2a} \Rightarrow a = \frac{\mu}{2\mu - v^2} \Rightarrow r = \frac{p}{1 + e \cos \theta}$$

## Example 14

A satellite position and velocity vector (SV) at some instant if time is given in the ECI.  
Determine its corresponding Orbital elements (OE).

$$\mathbf{r} = -6045\hat{\mathbf{i}} - 3490\hat{\mathbf{j}} + 2500\hat{\mathbf{k}} \text{ (km)}$$

$$\mathbf{v} = -3.457\hat{\mathbf{i}} + 6.618\hat{\mathbf{j}} + 2.533\hat{\mathbf{k}} \text{ (km/s)}$$

### Solution

Step 1:

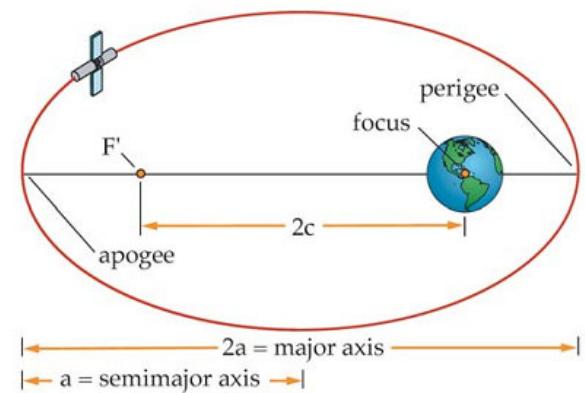

$$r = \sqrt{\mathbf{r} \cdot \mathbf{r}} = \sqrt{(-6045)^2 + (-3490)^2 + 2500^2} = 7414 \text{ km}$$

Step 2:

$$v = \sqrt{\mathbf{v} \cdot \mathbf{v}} = \sqrt{(-3.457)^2 + 6.618^2 + 2.533^2} = 7.884 \text{ km/s}$$

Step 3:

$$v_r = \frac{\mathbf{v} \cdot \mathbf{r}}{r} = \frac{(-3.457) \cdot (-6045) + 6.618 \cdot (-3490) + 2.533 \cdot 2500}{7414} = 0.5575 \text{ km/s}$$

# Example 14

Step 4:

$$\mathbf{h} = \mathbf{r} \times \mathbf{v} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -6045 & -3490 & 2500 \\ -3.457 & 6.618 & 2.533 \end{vmatrix} = -25,380\hat{\mathbf{i}} + 6670\hat{\mathbf{j}} - 52,070\hat{\mathbf{k}} \text{ (km}^2/\text{s})$$

Step 5:

$$h = \sqrt{\mathbf{h} \cdot \mathbf{h}} = \sqrt{(-25,380)^2 + 6670^2 + (-52,070)^2} = [58,310 \text{ km}^2/\text{s}]$$

Step 6:

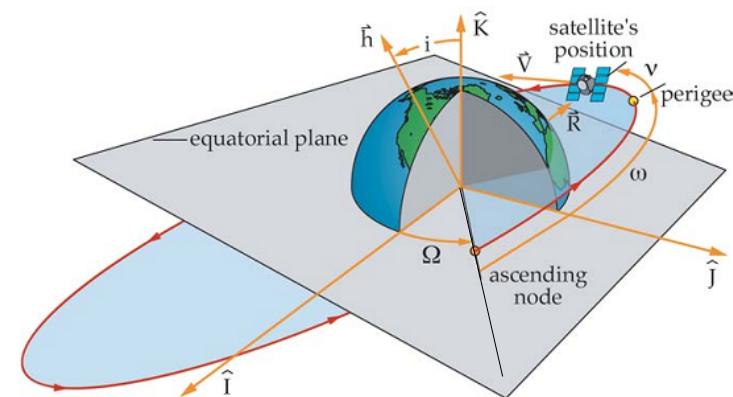

$$i = \cos^{-1} \frac{h_z}{h} = \cos^{-1} \left( \frac{-52,070}{58,310} \right) = [153.2^\circ]$$

Step 7:

$$\mathbf{N} = \hat{\mathbf{k}} \times \mathbf{h} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 0 & 1 \\ -25,380 & 6670 & -52,070 \end{vmatrix} = -6670\hat{\mathbf{i}} - 25,380\hat{\mathbf{j}} \text{ (km}^2/\text{s})$$

Step 8:

$$N = \sqrt{\mathbf{N} \cdot \mathbf{N}} = \sqrt{(-6670)^2 + (-25,380)^2} = 26,250 \text{ km}^2/\text{s}$$

# Example 14

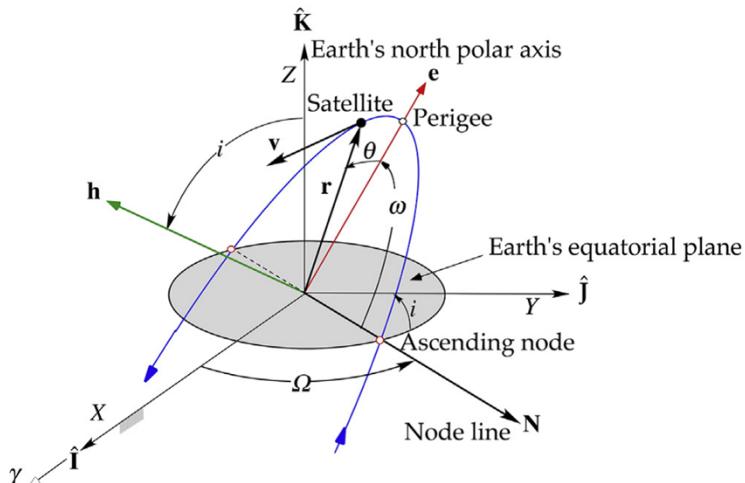

Step 9:

$$\Omega = \cos^{-1} \frac{N_x}{N} = \cos^{-1} \left( \frac{-6670}{26,250} \right) = 104.7^\circ \text{ or } 255.3^\circ$$

Step 10:

$$\begin{aligned}\mathbf{e} &= \frac{1}{\mu} \left[ \left( v^2 - \frac{\mu}{r} \right) \mathbf{r} - r \mathbf{v} \cdot \mathbf{v} \right] \\ &= \frac{1}{398,600} \left[ \left( 7.884^2 - \frac{398,600}{7414} \right) \left( -6045\hat{\mathbf{i}} - 3490\hat{\mathbf{j}} + 2500\hat{\mathbf{k}} \right) \right. \\ &\quad \left. - (7414)(0.5575) \left( -3.457\hat{\mathbf{i}} + 6.618\hat{\mathbf{j}} + 2.533\hat{\mathbf{k}} \right) \right] \\ \mathbf{e} &= -0.09160\hat{\mathbf{i}} - 0.1422\hat{\mathbf{j}} + 0.02644\hat{\mathbf{k}}\end{aligned}$$

Step 11:

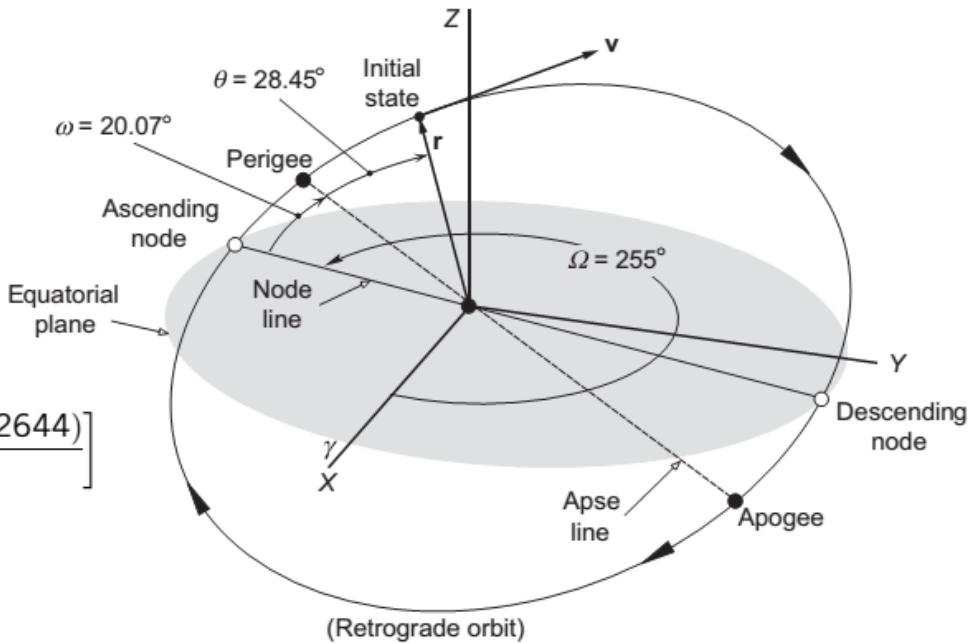

$$e = \sqrt{\mathbf{e} \cdot \mathbf{e}} = \sqrt{(-0.09160)^2 + (-0.1422)^2 + (0.02644)^2} = \boxed{0.1712}$$

## Example 14

Step 12:

$$\begin{aligned}\omega &= \cos^{-1} \frac{\mathbf{N} \cdot \mathbf{e}}{N e} \\ &= \cos^{-1} \left[ \frac{(-6670)(-0.09160) + (-25,380)(-0.1422) + (0)(0.02644)}{(26,250)(0.1712)} \right] \\ &= 20.07^\circ \text{ or } 339.9^\circ\end{aligned}$$

$e_Z > 0$

Step 13:

$$\begin{aligned}\theta &= \cos^{-1} \left( \frac{\mathbf{e} \cdot \mathbf{r}}{er} \right) = \cos^{-1} \left[ \frac{(-0.09160)(-6045) + (-0.1422)(-3490) + (0.02644)(2500)}{(0.1712)(7414)} \right] \\ &= 28.45^\circ \text{ or } 331.6^\circ\end{aligned}$$

$v_r > 0$

## Example 15

A satellite position and eccentricity vectors is given in the ECI at some instant.

If  $\gamma < 0$ , determine the orbital plane dihedral angles, i.e  $(i, \Omega, \omega)$ .

$$[\mathbf{r}]^{ECI} = [-6634.2 \ -1261.8 \ -5230.9]^T \text{ km}$$

$$[\mathbf{e}]^{ECI} = [-0.4097 \ -0.4875 \ -0.6364]^T$$

**Solution:**

$$\cos \theta = \mathbf{e} \cdot \mathbf{r} / (e r) \rightarrow \theta = -30 \text{ deg}$$

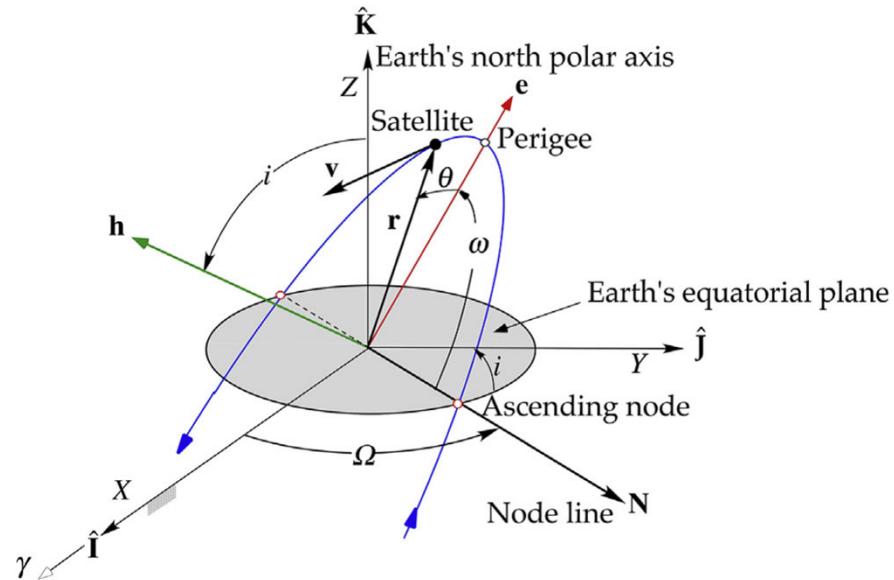

$$\mathbf{u}_h = \frac{\mathbf{r} \times \mathbf{e}}{|\mathbf{r} \times \mathbf{e}|} = \begin{bmatrix} -0.4545 & -0.5417 & 0.7071 \end{bmatrix}^T$$

$$\cos(i) = \mathbf{u}_h(3) \rightarrow i = 45 \text{ deg}$$

$$\mathbf{n} = \mathbf{K} \times \mathbf{u}_h = [0.5417 \ -0.4545 \ 0]^T$$

$$\cos(\Omega) = \mathbf{n}(1) \xrightarrow{n(2)<0} \Omega = 360 - 57.2 = 302.8 \text{ deg}$$

$$\cos \omega = \mathbf{n} \cdot \mathbf{e} / e \xrightarrow{e(3)<0} \omega = 360 - 90 \text{ deg} = 270 \text{ deg}$$

# OE to State Vector transformation

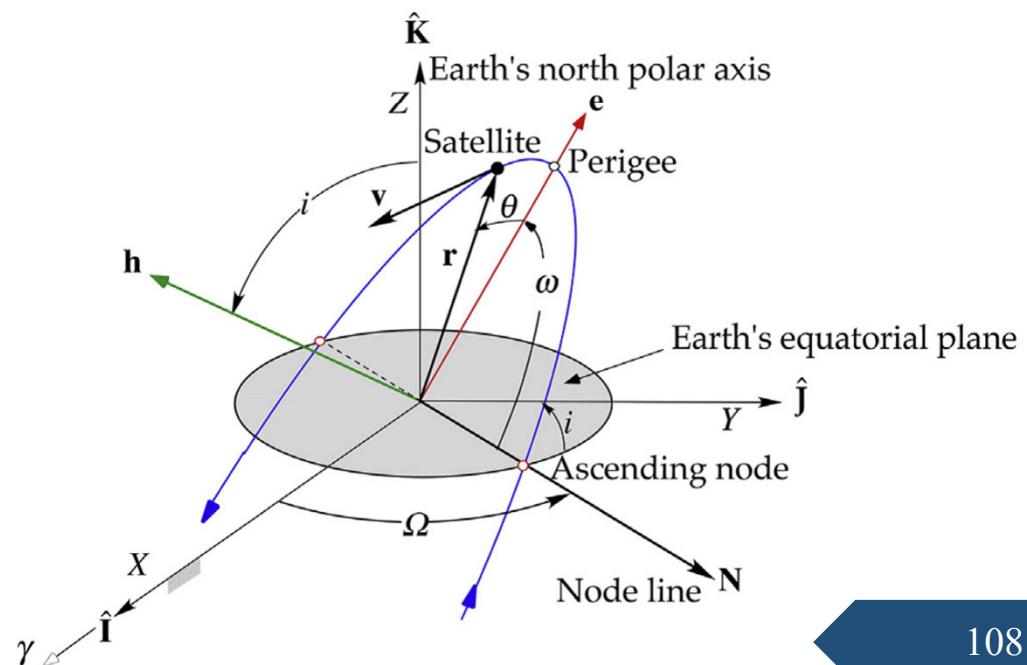

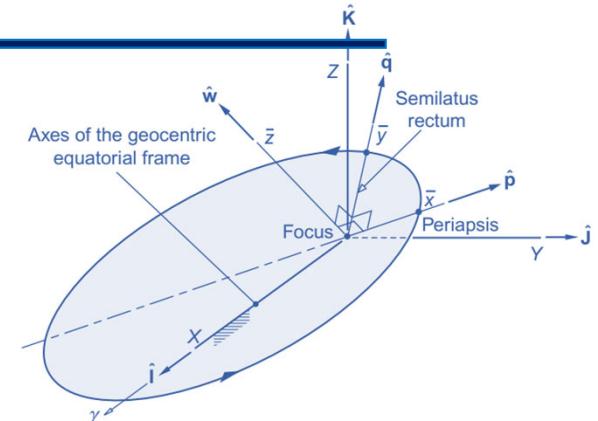

In some instances, it is desired to convert a satellite Orbital elements (OE) to its corresponding State vector (SV). Inverse transformation from OE to SV is possible using a transformation matrix between the Perifocel CS and ECI. The problem is defined as :

Given the satellite OE, find its corresponding SV.

$$\alpha = [a \ e \ i \ \Omega \ \omega \ \theta]^T \Rightarrow X = [\vec{r} \ \vec{v}]^T$$

Coordination in the PCS :  $\bar{x} \equiv PCS; X \equiv ECI$

$$\left\{ \begin{array}{l} \mathbf{r} = \bar{x}\hat{\mathbf{p}} + \bar{y}\hat{\mathbf{q}} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} (\cos\theta\hat{\mathbf{p}} + \sin\theta\hat{\mathbf{q}}) \\ \mathbf{v} = \dot{\bar{x}}\hat{\mathbf{p}} + \dot{\bar{y}}\hat{\mathbf{q}} = \frac{\mu}{h} [-\sin\theta\hat{\mathbf{p}} + (e + \cos\theta)\hat{\mathbf{q}}] \end{array} \right. \rightarrow \left\{ \begin{array}{l} \{\mathbf{r}\}_{\bar{x}} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} \begin{Bmatrix} \cos\theta \\ \sin\theta \\ 0 \end{Bmatrix} \\ \{\mathbf{v}\}_{\bar{x}} = \frac{\mu}{h} \begin{Bmatrix} -\sin\theta \\ e + \cos\theta \\ 0 \end{Bmatrix} \end{array} \right.$$

# Transformation between ECI and PCS

In other words given the OE, one can simply generate the Position and Velocity vector of the satellite in the PCS. Next via a Transformation matrix presented in the next slide, this data can be converted into the ECI coordinate system.

$$[\mathbf{r}]^{PCS} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} \begin{bmatrix} \cos\theta \\ \sin\theta \\ 0 \end{bmatrix}$$

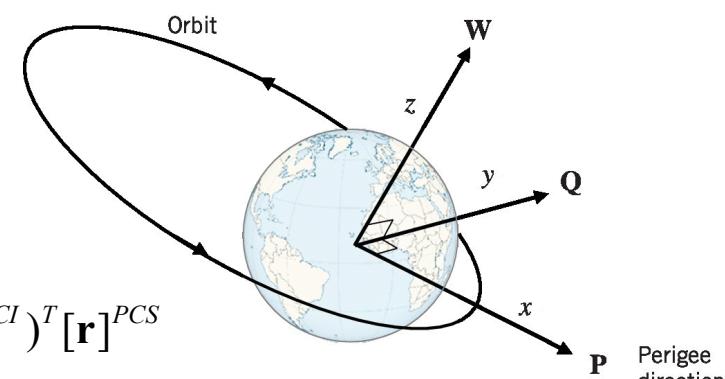

$$[\mathbf{r}]^{ECI} = \mathbf{T}^{ECI-PCS} [\mathbf{r}]^{PCS} = (\mathbf{T}^{PCS-ECI})^T [\mathbf{r}]^{PCS}$$

$$[\mathbf{r}]^{PCS} = \begin{Bmatrix} \bar{x} \\ \bar{y} \\ 0 \end{Bmatrix} = \mathbf{T}^{PCS-ECI} [\mathbf{r}]^{ECI}$$

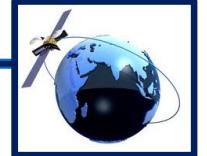

$$[\mathbf{v}]^{PCS} = \frac{\mu}{h} \begin{bmatrix} -\sin\theta \\ e+\cos\theta \\ 0 \end{bmatrix}$$

$$[\mathbf{v}]^{ECI} = \mathbf{T}^{ECI-PCS} [\mathbf{v}]^{PCS} = (\mathbf{T}^{PCS-ECI})^T [\mathbf{v}]^{PCS}$$

$$[\mathbf{v}]^{PCS} = \begin{Bmatrix} \dot{\bar{x}} \\ \dot{\bar{y}} \\ 0 \end{Bmatrix} = \mathbf{T}^{PCS-ECI} [\mathbf{v}]^{ECI}$$

# Transformation Matrix between ECI and Perifocal CS

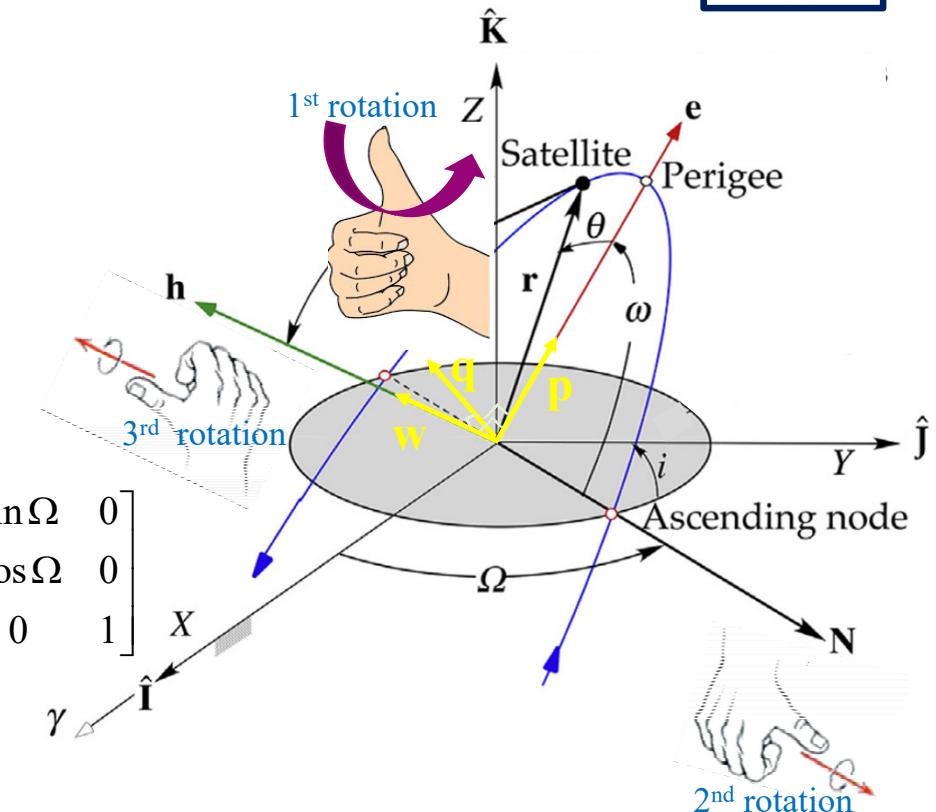

ECI to PCS Transformation

$$[\mathbf{Q}]_{\bar{x}\bar{x}} = \mathbf{T}^{PCS-ECI} = [\mathbf{R}_3(\omega)][\mathbf{R}_1(i)][\mathbf{R}_3(\Omega)]$$

3<sup>rd</sup> rotation      2<sup>nd</sup> rotation      1<sup>st</sup> rotation

$$[\mathbf{Q}]_{\bar{x}\bar{x}} = \mathbf{T}^{PCS-ECI} = \begin{bmatrix} \cos \omega & \sin \omega & 0 \\ -\sin \omega & \cos \omega & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos i & \sin i \\ 0 & -\sin i & \cos i \end{bmatrix} \begin{bmatrix} \cos \Omega & \sin \Omega & 0 \\ -\sin \Omega & \cos \Omega & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Note:  $[\mathbf{Q}]_{\bar{x}\bar{x}}^T = [\mathbf{Q}]_{\bar{x}\bar{x}}$

## Example 16

Consider an Earth orbiting satellite whose OE at one instant is provided below.

Determine its corresponding SV in the ECI coordinate system.

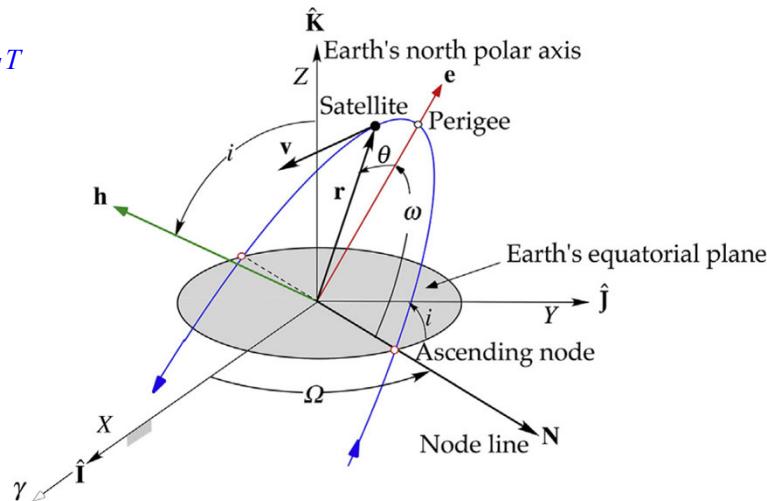

$$\alpha = [h = 8 \times 10^4 \text{ Km}^2/\text{s} \quad e = 1.4 \quad i = 30^\circ \quad \Omega = 40^\circ \quad \omega = 60^\circ \quad \theta = 30^\circ]^T$$

Coordination in the PCS :  $\bar{x} \equiv PCS; X \equiv ECI$

$$\begin{cases} \mathbf{r} = \bar{x}\hat{\mathbf{p}} + \bar{y}\hat{\mathbf{q}} = \frac{h^2}{\mu} \frac{1}{1+e\cos\theta} (\cos\theta\hat{\mathbf{p}} + \sin\theta\hat{\mathbf{q}}) \\ \mathbf{v} = \dot{\bar{x}}\hat{\mathbf{p}} + \dot{\bar{y}}\hat{\mathbf{q}} = \frac{\mu}{h} [-\sin\theta\hat{\mathbf{p}} + (e + \cos\theta)\hat{\mathbf{q}}] \\ \rightarrow \begin{cases} \{\mathbf{r}\}_{\bar{x}} = \{6285 \quad 3628.6 \quad 0\} \text{ Km} \\ \{\mathbf{v}\}_{\bar{x}} = \{-2.4913 \quad 11.29 \quad 0\} \text{ Km/s} \end{cases} \end{cases}$$

$$[\mathbf{Q}]_{X\bar{x}} = \mathbf{T}^{PCS-ECI} = \begin{bmatrix} \cos\omega & \sin\omega & 0 \\ -\sin\omega & \cos\omega & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos i & \sin i \\ 0 & -\sin i & \cos i \end{bmatrix} \begin{bmatrix} \cos\Omega & \sin\Omega & 0 \\ -\sin\Omega & \cos\Omega & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} -0.09907 & -0.94175 & 0.3214 \\ 0.8959 & 0.2249 & -0.383 \\ 0.433 & 0.25 & 0.866 \end{bmatrix}$$

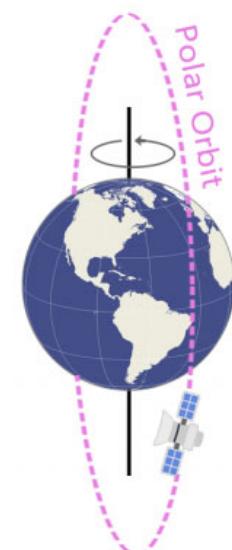

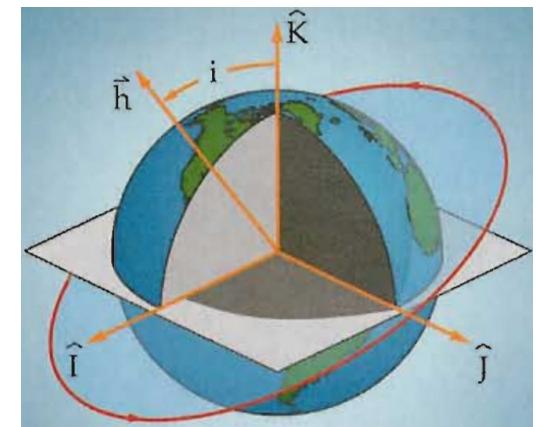

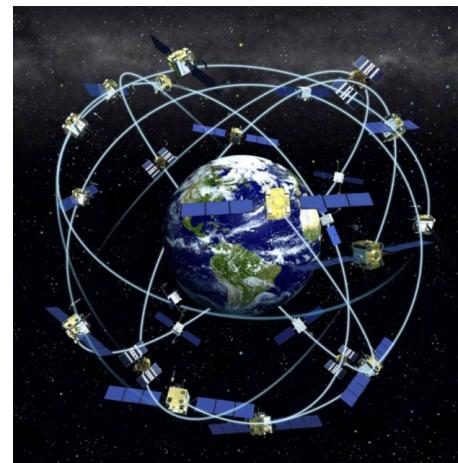

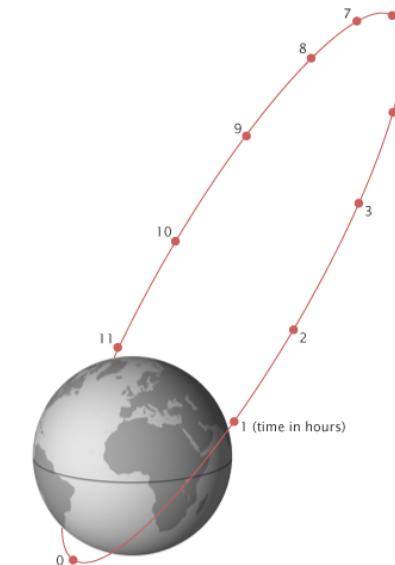

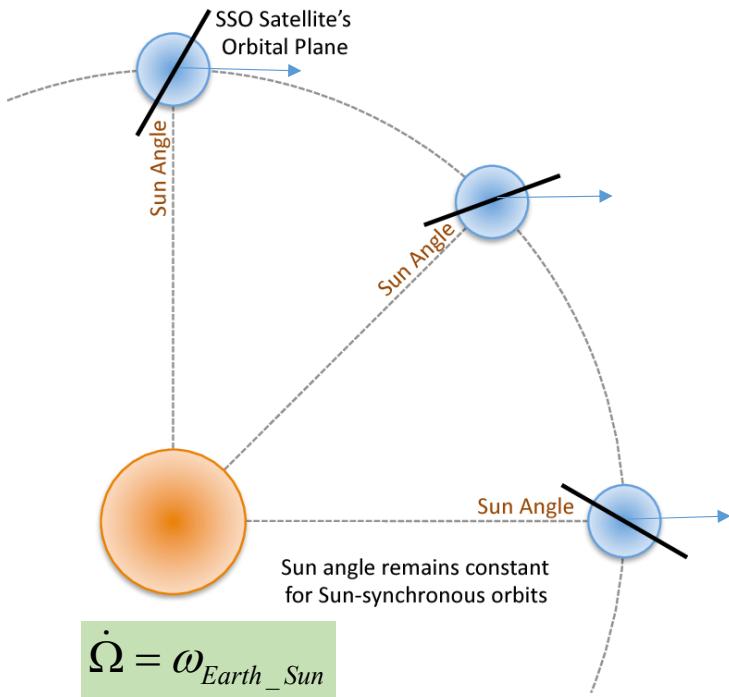

$$\rightarrow \begin{cases} \{\mathbf{r}\}_X = [\mathbf{Q}]_{\bar{x}X} \{6285 \quad 3628.6 \quad 0\}^T \text{ Km} = \{-4040 \quad 4815 \quad 3629\}^T \text{ Km} \\ \{\mathbf{v}\}_X = [\mathbf{Q}]_{\bar{x}X} \{-2.4913 \quad 11.29 \quad 0\}^T = \{-10.39 \quad -4.772 \quad 1.744\}^T \text{ Km/s} \end{cases}$$

# Orbital Classifications

## Orbit Classification in terms of Inclination

- Equatorial and Polar Orbits
- Prograde/ Retrograde Orbits
- Sun Synchronous Orbits

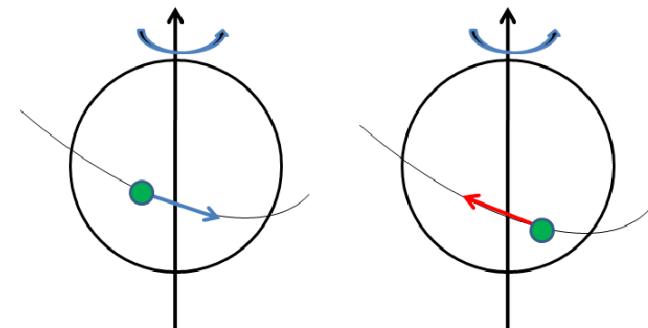

# Orbit Classification in terms of Inclination

## Prograde/Direct Orbits:

- Natural bodies within the Solar system : All of the planets and most of the other objects that orbit the Sun, with the exception of many comets.
- Artificial Satellites: Almost all communication satellites .

## Retrograde Orbits:

Most commercial Earth observing satellites,  
Sun-synchronous Orbits (useful for imaging, spy, and weather satellites. )

a) Prograde orbit

b) Retrograde orbit

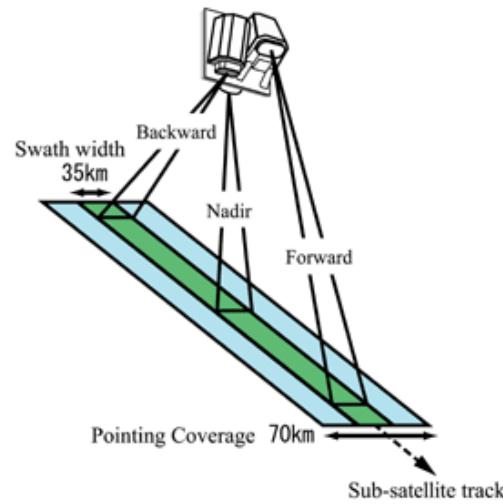

$$0 < i < 90^\circ \Rightarrow \text{Prograde Orbit} \text{ Or } 90^\circ < i < 180^\circ \Rightarrow \text{Retrograde Orbit}$$

# Ground Track

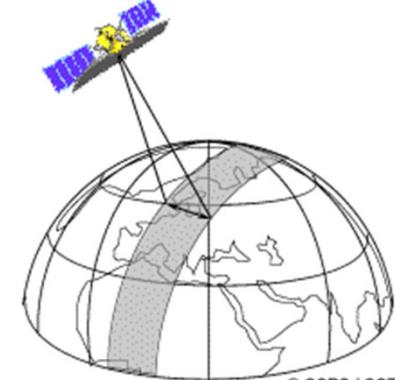

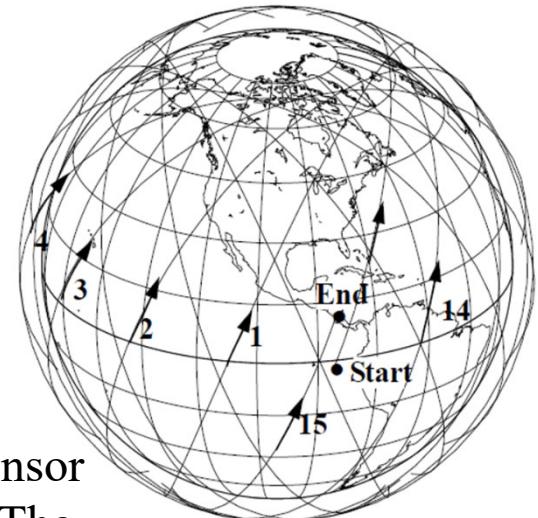

Ground track (GT) or ground trace is the projection of the satellite's orbit onto the surface of the Earth. Some of its properties and advantages are:

- GT is a powerful tool for determining orbit position and location relative to a ground site.
- Typically, satellites have a roughly sinusoidal ground track.
- Ground track of a SC can take a number of different forms, depending on the values of the orbital elements.

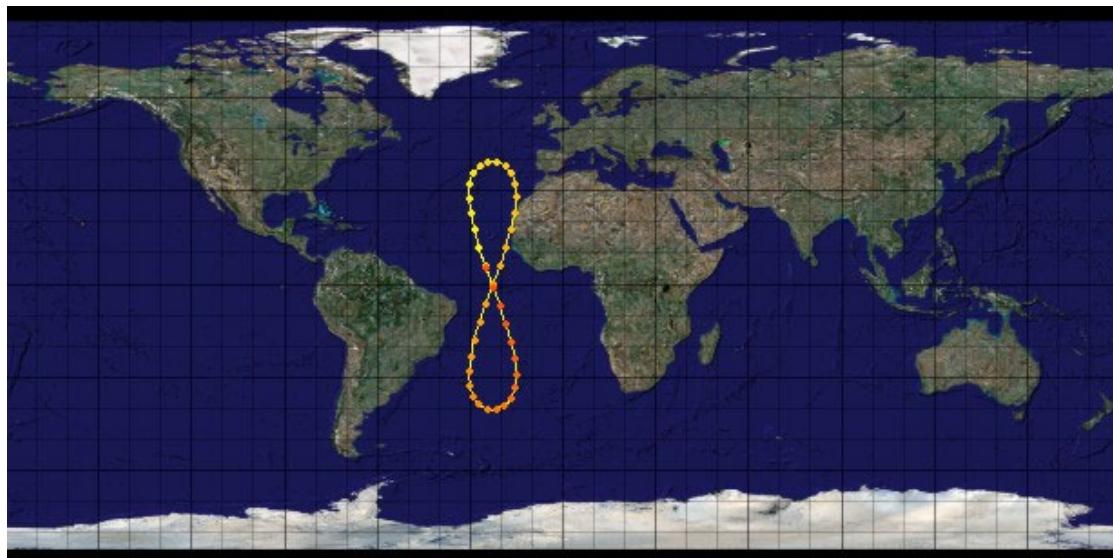

As a satellite revolves around the Earth, the sensor "sees" a certain portion of the Earth's surface. The area imaged on the surface, is referred to as the **swath**. Imaging swaths for space borne sensors generally vary between tens and hundreds of kilometers wide. Due to Earth rotation, the satellite swath covers a new area with each consecutive pass or orbit around the Earth.

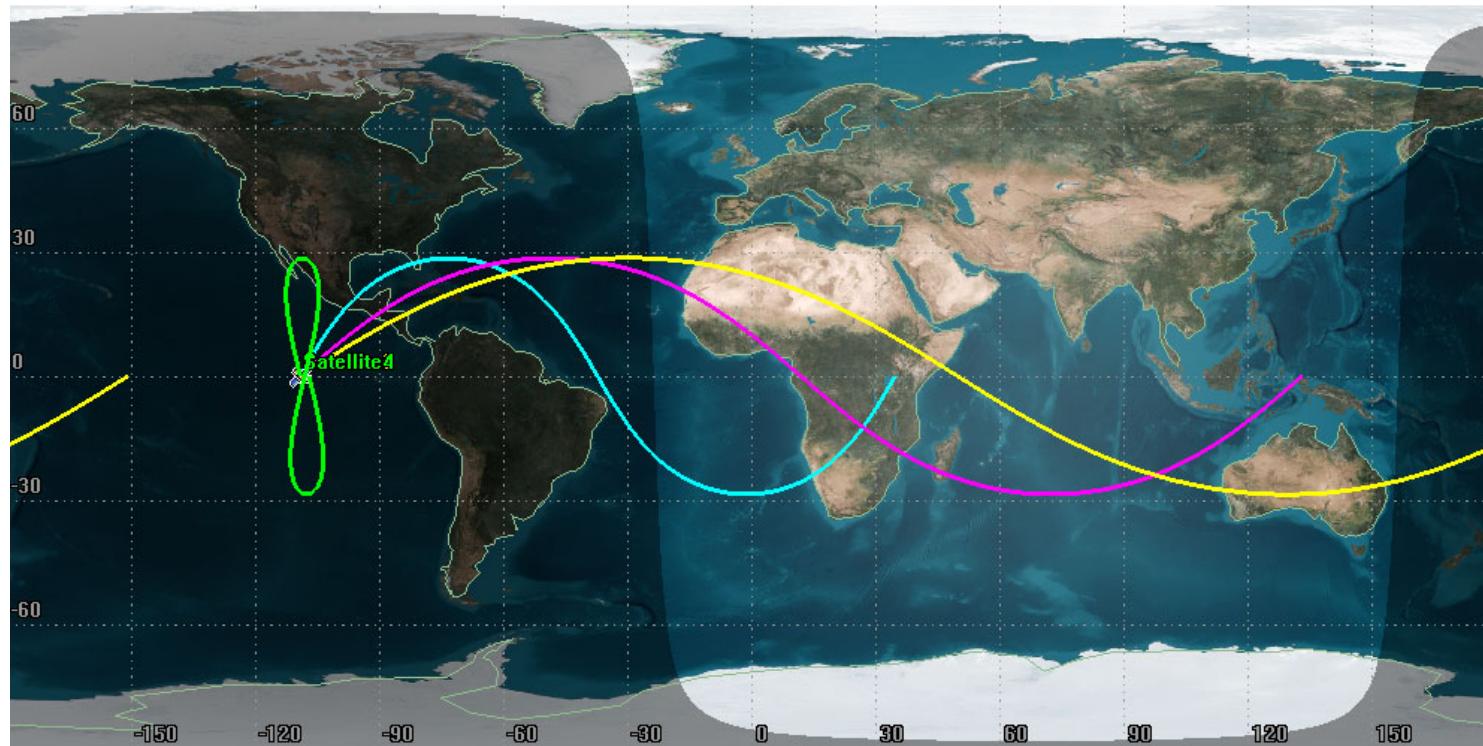

# Geosynchronous Ground Track

In general a geosynchronous orbit (GSO) is an Earth-centered circular or elliptical [orbit](#) with an [orbital period](#) that matches the [Earth's rotation](#) rate (23 hours, 56 minutes, and 4 seconds denotes by one [sidereal day](#)). This synchronization means that a satellite in GSO returns to the same position after a period of one sidereal day. During the course of a day, the satellite position in the sky may remain [still or trace out a path typically in a figure-8 form](#) whose precise characteristics depend on the orbit's [inclination](#) and [eccentricity](#). A circular geosynchronous orbit has a constant altitude of 35,786 km (22,236 mi), and all geosynchronous orbits share that semi-major axis. A special case of geosynchronous orbit is the [geostationary orbit](#), which is a circular geosynchronous orbit in the Earth's [equatorial plane](#). A satellite in a geostationary orbit remains in the same position in the sky to observers on the surface that is a single point on the Earth's equator.

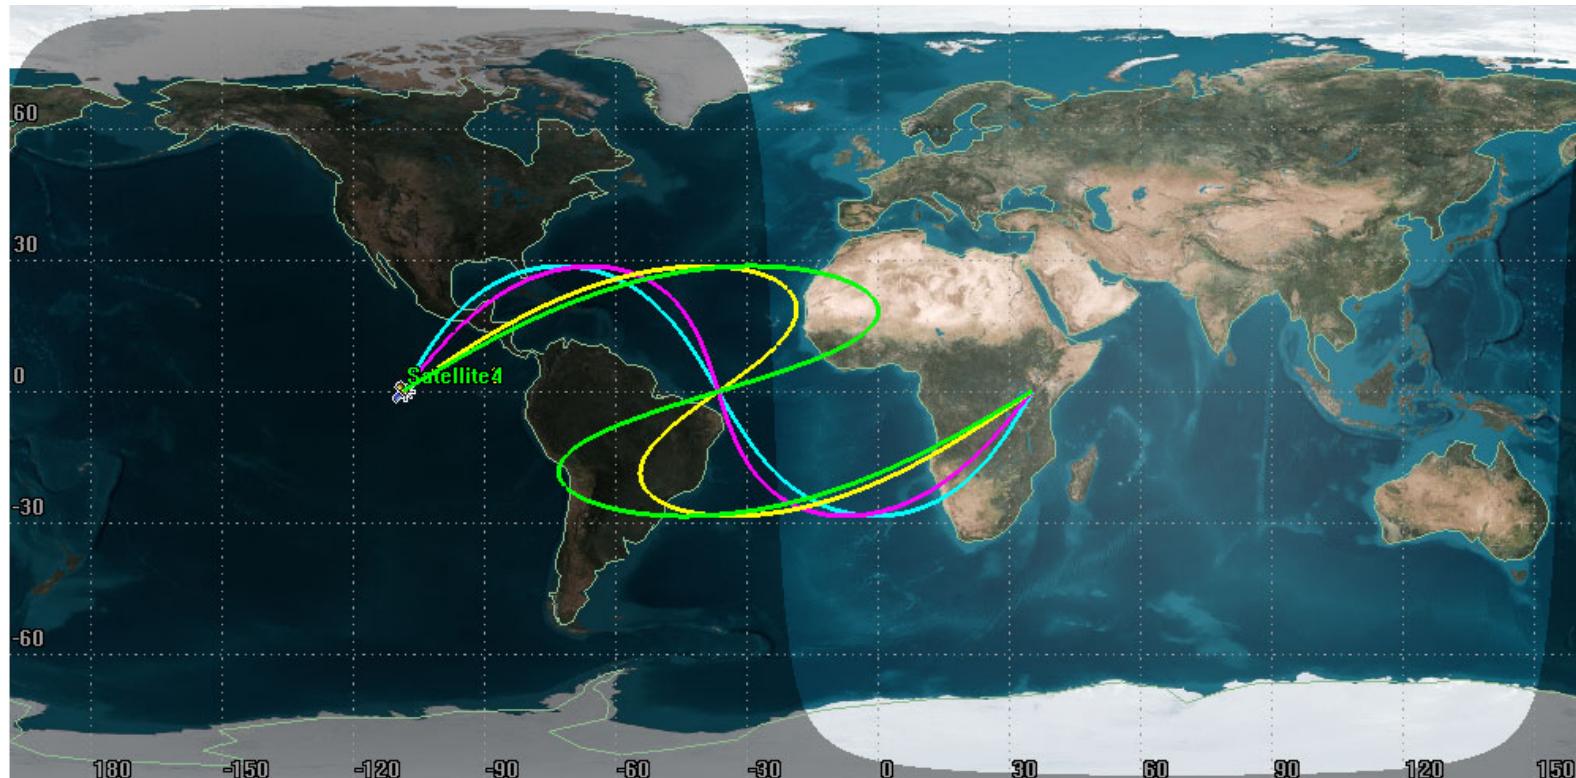

# Ground Track

- Effect of the semi-major axis

- $a = 10000 \text{ km}$
- $a = 20000 \text{ km}$
- $a = 30000 \text{ km}$
- $a = 42000 \text{ km}$

# Ground Track : Effect of Eccentricity

$e = 0$

$e = 0.1$

$e = 0.5$

$e = 0.7$

# Molniya Ground Track

The Molniya is a type of satellite orbit designed to provide communications and remote sensing coverage over high latitudes. Its orbit is designed such that its argument of perigee is fixed. An orbit designed in this manner is called a frozen orbit.

It is a **highly elliptical orbit** with the following properties:

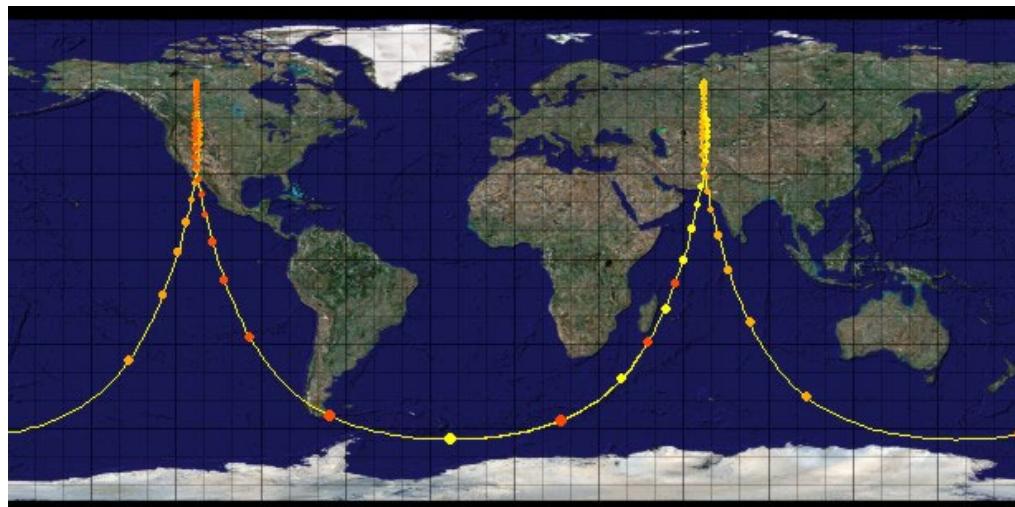

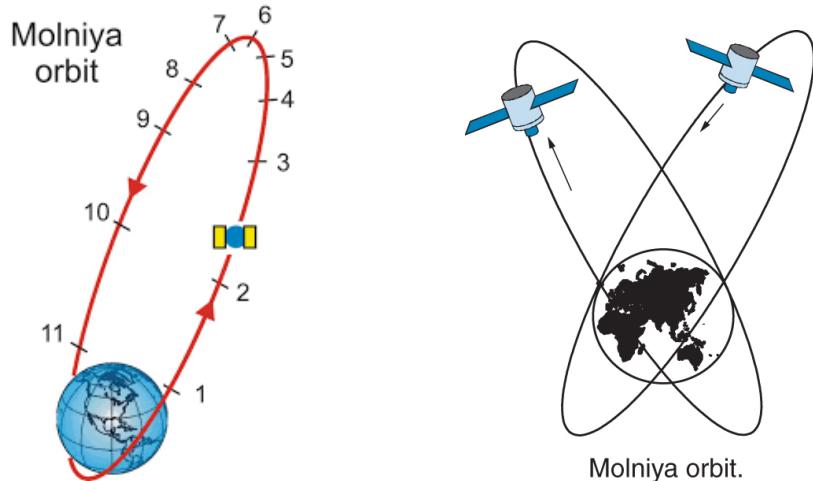

Argument of perigee:  $270^\circ$

Inclination:  $63.4^\circ$

Period: 718 minutes

Eccentricity: 0.74

Semi-major axis: 26,600 km (16,500 mi)

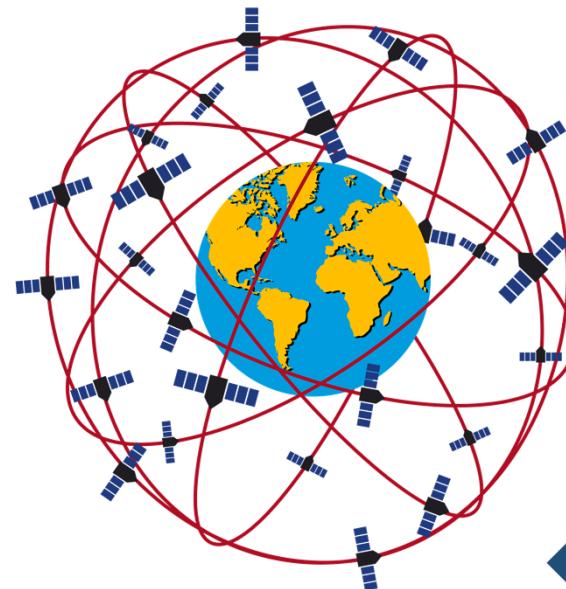

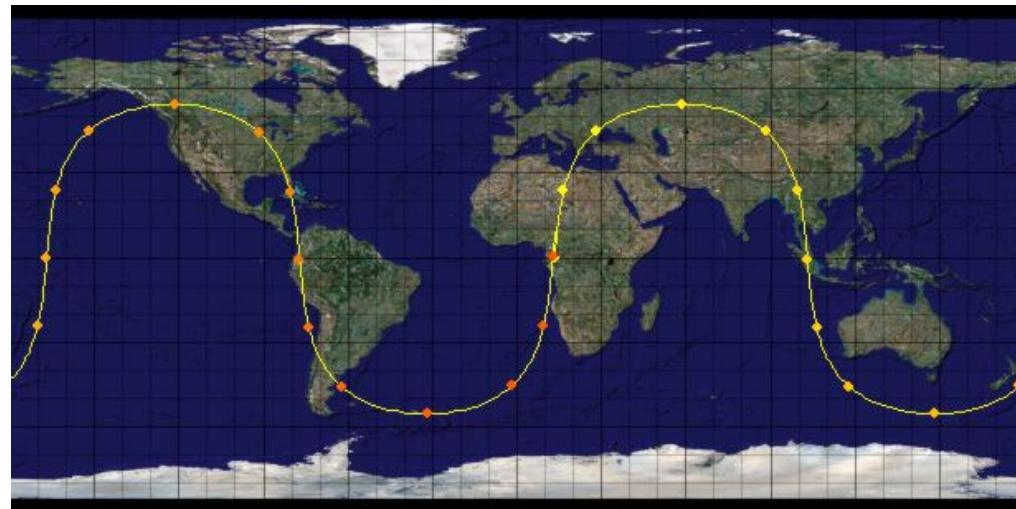

# GPS Orbit Ground Track

The satellites in the GPS constellation are arranged into six equally-spaced orbital planes surrounding the Earth. Each plane contains four "slots" occupied by baseline satellites. This 24 slot arrangement ensures users can view at least four satellites from virtually any point on the planet.

- The altitude of each of the 24 space vehicles providing the GPS signal is 20200 km.
- The satellites are distributed equally among six circular orbital planes, which have an inclination of approximately  $55^\circ$  and are separated by  $60^\circ$ .

# Ground Track Computations

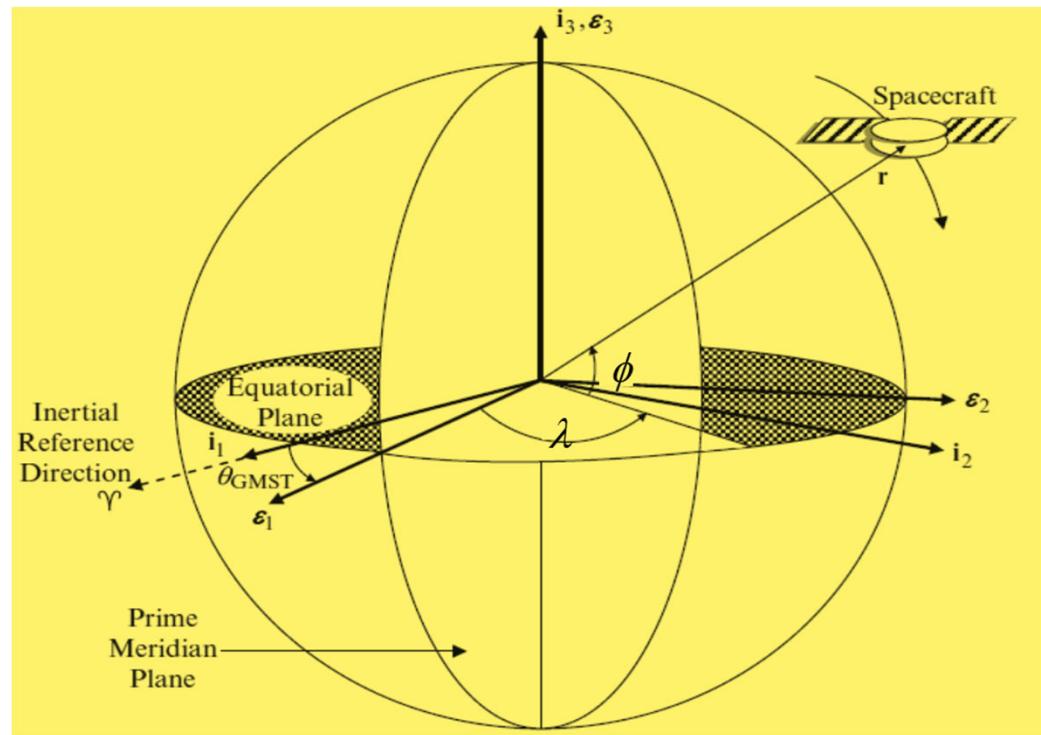

Ground track (GT) or ground trace is the projection of the satellite's orbit onto the surface of the Earth.

$$[\mathbf{R}_3(\theta)] = \begin{bmatrix} \cos \theta & \sin \theta & 0 \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Where :

$$\theta = \theta_{GMST} + \omega_E(t - t_0)$$
